# Writing VHDL for RTL Synthesis 

Stephen A. Edwards, Columbia University

December 4, 2007

The name VHDL is representative of the language itself: it is a two-level acronym that stands for VHSIC Hardware Description Language; VHSIC stands for very high speed integrated circuit. The language is vast, verbose, and was originally designed for modeling digital systems for simulation. As a result, the full definition of the language [1] is much larger than what we are concerned with here because many constructs in the language (e.g., variables, arbitrary events, floating-point types, delays) do not have hardware equivalents and hence not synthesizable.

Instead, we focus here on a particular dialect of VHDL dictated in part by the IEEE standard defining RTL synthesis [2]. Even within this standard, there are many equivalent ways to do essentially the same thing (e.g., define a process representing edgesensitive logic). This document presents a particular idiom that works; it does not try to define all possible synthesizable VHDL specifications.

## 1 Structure

Much like a C program is mainly a series of function definitions, a VHDL specification is mainly a series of entity/architecture definition pairs. An entity is an object with a series of input and output ports that represent wires or busses, and an architecture is the "guts" of an entity, comprising concurrent assignment statements, processes, or instantiations of other entities.

Concurrent assignment statements that use logical expressions to define the values of signals are one of the most common things in architectures. VHDL supports the logical operators and, or, nand, nor, xnor, xnor, and not.

```
library ieee; -- add this to the IEEE library
use ieee.std_logic_1164.all; -- includes std_ulogic
entity full_adder is
    port(a, b, c : in std_ulogic;
            sum, carry : out std_ulogic);
end full_adder;
architecture imp of full_adder is
begin
    sum <= (a xor b) xor c; -- combinational logic
    carry <= (a and b) or (a and c) or (b and c);
end imp;
```

### 1.1 Components

Once you have defined an entity, the next thing is to instantiate it as a component within another entity's architecture.

The interface of the component must be defined in any architecture that instantiates it. Then, any number of port map statements create instances of that component. Here is how to connect two of the full adders to give a two-bit adder:

```
library ieee;
use ieee.std_logic_1164.all;
entity add2 is
    port (
            A, B : in std_logic_vector(1 downto 0);
            C : out std_logic_vector(2 downto 0));
end add2;
architecture imp of add2 is
    component full_adder
        port (
                a, b, c : in std_ulogic;
                sum, carry : out std_ulogic);
    end component;
    signal carry : std_ulogic;
begin
    bit0 : full_adder port map (
        a => A(0),
        b => B(0),
        c => '0',
        sum => C(0),
        carry => carry);
    bit1 : full_adder port map (
        a => A(1),
        b => B(1),
        c => carry,
        sum => C(1),
        carry => C(2));
end imp;
```

### 1.2 Multiplexers

The when...el se construct is one way to specify a multiplexer.

```
library ieee;
use ieee.std_logic_1164.all;
entity multiplexer_4_1 is
    port(in0, in1, in2, in3 : in std_ulogic_vector(15 downto 0);
            s0, s1 : in std_ulogic;
            z : out std_ulogic_vector(15 downto 0));
end multiplexer_4_1;
architecture imp of multiplexer_4_1 is
begin
    z <= in0 when (s0 = '0' and s1 = '0') else
            in1 when (s0 = '1' and s1 = '0') else
            in2 when (s0 = '0' and s1 ='1') else
            in3 when (s0 = '1' and s1 = '1') else
            "XXXXXXXXXXXXXXXX";
end imp;
```

The with...select is another way to describe a multiplexer.

```
architecture usewith of multiplexer_4_1 is
    signal sels : std_ulogic_vector(1 downto 0); -- Local wires
begin
    sels <= s1 & s0; -- vector concatenation
    with sels select
        z <=
        in0 when "O0",
        in1 when "01",
        in2 when "10",
        in3 when "11",
        "XXXXXXXXXXXXXXXX" when others;
end usewith;
```

### 1.3 Decoders

Often, you will want to take a set of bits encoded in one way and represent them in another. For example, the following one-of-eight decoder takes three bits and uses them to enable one of eight.

```
library ieee;
use ieee.std_logic_1164.all;
entity dec1_8 is
port (
    sel : in std_logic_vector(2 downto 0);
    res : out std_logic_vector(7 downto 0));
end dec1_8;
architecture imp of dec1_8 is
begin
    res <= "00000001" when sel = "000" else
        "00000010" when sel = "001" else
        "00000100" when sel = "010" else
        "00001000" when sel = "011" else
        "00010000" when sel = "100" else
        "00100000" when sel = "101" else
        "01000000" when sel = "110" else
        "10000000";
end imp;
```

### 1.4 Priority Encoders

A priority encoder returns a binary value that indicates the highest set bit among many. This implementation says the output when none of the bits are set is a "don't-care," meaning the synthesis system is free to generate any output it wants for this case.

```
library ieee;
use ieee.std_logic_1164.all;
entity priority is
    port (
        sel : in std_logic_vector(7 downto 0);
        code : out std_logic_vector(2 downto 0));
end priority;
architecture imp of priority is
begin
    code <= "000" when sel(0) = '1' else
                        "001" when sel(1) = '1' else
                        "010" when sel(2) = '1' else
                        "011" when sel(3) = '1' else
                        "100" when sel(4) = '1' else
                        "101" when sel(5) = '1' else
            "110" when sel(6) = '1' else
            "111" when sel(7) = '1' else
                        "---"; -- output is a "don't care"
end imp;
```

### 1.5 Arithmetic Units

VHDL has extensive support for arithmetic. Here is an unsigned 8-bit adder with carry in and out. By default VHDL's + operator returns a result that is the same width as its arguments, so it is necessary to zero-extend them to get the ninth (carry) bit out. One way to do this is to convert the arguments to integers, add them, then convert them back.

```
library ieee;
use ieee.std_logic_1164.all;
use ieee.std_logic_arith.all;
use ieee.std_logic_unsigned.all;
entity adder is
    port (
        A, B : in std_logic_vector(7 downto 0);
        CI : in std_logic;
        SUM : out std_logic_vector(7 downto 0);
        CO : out std_logic);
end adder;
architecture imp of adder is
signal tmp : std_logic_vector(8 downto 0);
begin
    tmp <= conv_std_logic_vector((conv_integer(A) + conv_integer(B) +
                                    conv_integer(CI)), 9);
    SUM <= tmp(7 downto 0);
    CO <= tmp(8);
end imp;
```

A very primitive ALU might perform either addition or subtraction:

```
library ieee;
use ieee.std_logic_1164.all;
use ieee.std_logic_unsigned.all;
entity alu is
    port (
        A, B : in std_logic_vector(7 downto 0);
        ADD : in std_logic;
        RES : out std_logic_vector(7 downto 0));
end alu;
architecture imp of alu is
begin
    RES <= A + B when ADD = '1' else
            A - B;
end imp;
```

VHDL provides the usual arithmetic comparison operators. Note that signed and unsigned versions behave differently.

```
library ieee;
use ieee.std_logic_1164.all;
use ieee.std_logic_unsigned.all;
entity comparator is
    port (
        A, B : in std_logic_vector(7 downto 0);
        GE : out std_logic);
end comparator;
architecture imp of comparator is
begin
    GE <= '1' when A >= B else '0';
end imp;
```

Multiplication and division is possible, but is very costly in area and can be very slow.

### 1.6 Generate statements

To get an unusual array, say that for a 4-bit ripple-carry adder, use a generate construct, which expands its body into multiple gates when synthesized.

```
library ieee;
use ieee.std_logic_1164.all;
entity rippleadder is
    port (a, b : in std_ulogic_vector(3 downto 0);
        cin : in std_ulogic;
        sum : out std_ulogic_vector(3 downto 0);
        cout : out std_ulogic);
end rippleadder;
architecture imp of rippleadder is
    signal c : std_ulogic_vector(4 downto 0);
begin
    c(0) <= cin;
    G1: for m in 0 to 3 generate
        sum(m) <= a(m) xor b(m) xor c(m);
        c(m+1) <= (a(m) and b(m)) or (b(m) and c(m)) or (a(m) and c(m));
    end generate G1;
    cout <= c(4);
end imp;
```

## 2 State-holding Elements

Although there are many ways to express something that behaves like a flip-flop in VHDL, this is guaranteed to synthesize as you would like

```
library ieee;
use ieee.std_logic_1164.all;
entity flipflop is
    port (Clk, D : in std_ulogic;
            Q : out std_ulogic);
end flipflop;
architecture imp of flipflop is
begin
    process (Clk) -- Process made sensitive to Clk
    begin
        if (Clk'event and Clk = '1') then -- Rising edge
            Q <= D;
        end if;
    end process P1;
end imp;
```

Often, you want a synchronous reset on the flip-flop.

```
library ieee;
use ieee.std_logic_1164.all;
entity flipflop_reset is
    port (Clk, Reset, D : in std_ulogic;
                Q : out std_ulogic);
end flipflop_reset;
architecture imp of flipflop_reset is
begin
    P1: process (Clk)
    begin
            if (Clk'event and Clk = '1') then
                if (Reset = '1') then Q <= '0';
                else Q <= D;
                end if;
            end if;
    end process P1;
end imp;
```

### 2.1 Counters

Counters are often useful for delays, dividing clocks, and many other uses. Here is code for a four-bit unsigned up counter with a synchronous reset:

```
library ieee;
use ieee.std_logic_1164.all;
use ieee.std_logic_unsigned.all;
entity counter is
    port(
        Clk, Reset : in std_logic;
        Q : out std_logic_vector(3 downto 0)
    );
end counter;
architecture imp of counter is
    signal count : std_logic_vector(3 downto 0);
    begin
        process (Clk)
        begin
            if (Clk'event and Clk = '1') then
                    if (Reset ='1') then
                        count <= "0000";
                else
                        count <= count + 1;
                end if;
            end if;
        end process;
    Q <= count;
end imp;
```

### 2.2 Shift Registers

Here is code for an eight-bit shift register with serial in and out.

```
library ieee;
use ieee.std_logic_1164.all;
entity shifter is
    port (
        Clk : in std_logic;
        SI : in std_logic;
        SO : out std_logic);
end shifter;
architecture impl of shifter is
    signal tmp : std_logic_vector(7 downto 0);
begin
    process (Clk)
    begin
        if (Clk'event and Clk = '1') then
                for i in 0 to 6 loop -- Static loop, expanded at compile time
                    tmp(i+1) <= tmp(i);
                end loop;
                tmp(0) <= SI;
        end if;
    end process;
    SO <= tmp(7);
end impl;
```

### 2.3 RAMs

While large amounts of memory should be stored off-chip, small RAMs (say $32 \times 4$ bits) can be implemented directly. Here's how:

```
library ieee;
use ieee.std_logic_1164.all;
use ieee.std_logic_unsigned.all;
entity ram_32_4 is
    port (
        Clk : in std_logic;
        WE : in std_logic; -- Write enable
        EN : in std_logic; -- Read enable
        addr : in std_logic_vector(4 downto 0);
        di : in std_logic_vector(3 downto 0); -- Data in
        do : out std_logic_vector(3 downto 0)); -- Data out
end ram_32_4;
architecture imp of ram_32_4 is
    type ram_type is array(31 downto 0) of std_logic_vector(3 downto 0);
    signal RAM : ram_type;
begin
process (Clk)
begin
    if (Clk'event and Clk = '1') then
        if (en ='1') then
            if (we = '1') then
                RAM(conv_integer(addr)) <= di;
                do <= di;
            else
                do <= RAM(conv_integer(addr));
            end if;
        end if;
    end if;
end process;
end imp;
```

Occasionally, an initialized ROM is the most natural way to compute a certain function or store some data. Here is what a synchronous ROM looks like:

```
library ieee;
use ieee.std_logic_1164.all;
use ieee.std_logic_unsigned.all;
entity rom_32_4 is
    port (
        Clk : in std_logic;
        en : in std_logic; -- Read enable
        addr : in std_logic_vector(4 downto 0);
        data : out std_logic_vector(3 downto 0));
end rom_32_4;
architecture imp of rom_32_4 is
type rom_type is array (31 downto 0) of std_logic_vector(3 downto 0);
constant ROM : rom_type :=
    ("0001", "0010", "0011", "0100", "0101", "0110", "0111", "1000",
        "1001", "1010", "1011", "1100", "1101", "1110", "1111", "0001",
        "0010", "0011", "0100", "0101", "0110", "0111", "1000", "1001",
        "1010", "1011", "1100", "1101", "1110", "1111", "0000", "0010");
begin
process (Clk)
begin
    if (Clk'event and Clk = '1') then
        if (en ='1') then
            data <= ROM(conv_integer(addr));
        end if;
    end if;
end process;
end imp;
```

### 2.4 Finite-State Machines

Write a finite state machine as an entity containing two processes: a sequential process with if statement sensitive to the edge of the clock and a combinational process sensitive to all the inputs of the machine.

```
library ieee;
use ieee.std_logic_1164.all;
entity tlc is
    port (
        clk : in std_ulogic;
        reset : in std_ulogic;
        cars : in std_ulogic;
        short : in std_ulogic;
        long : in std_ulogic;
        highway_yellow : out std_ulogic;
        highway_red : out std_ulogic;
        farm_yellow : out std_ulogic;
        farm_red : out std_ulogic;
        start_timer : out std_ulogic);
end tlc;
architecture imp of tlc is
signal current_state, next_state : std_ulogic_vector(1 downto 0);
constant HG : std_ulogic_vector := "00";
constant HY : std_ulogic_vector := "01";
constant FY : std_ulogic_vector := "10";
constant FG : std_ulogic_vector := "11";
begin
P1: process (clk)
begin
    if (clk'event and clk = '1') then
        current_state <= next_state;
    end if;
end process P1;
P2: process (current_state, reset, cars, short, long)
begin
    if (reset = '1') then
        next_state <= HG;
        start_timer <= '1';
    else
        case current_state is
            when HG =>
                    highway_yellow <= '0';
                    highway_red <= '0';
                    farm_yellow <= '0';
                    farm_red <= '1';
                    if (cars = '1' and long = '1') then
                    next_state <= HY;
                    start_timer <= '1';
                    else
                        next_state <= HG;
                        start_timer <= '0';
                    end if;
                when HY =>
                    highway_yellow <= '1';
                    highway_red <= '0';
                    farm_yellow <= '0';
                    farm_red <= '1';
                    if (short = '1') then
                    next_state <= FG;
                    start_timer <= '1';
            else
                next_state <= HY;
                    start_timer <= '0';
            end if;
```

```
    when FG =>
    highway_yellow <= '0';
    highway_red <= '1';
    farm_yellow <= '0';
    farm_red <= '0';
    if (cars = '0' or long = '1') then
                next_state <= FY;
                start_timer <= '1';
    else
                next_state <= FG;
                start_timer <= '0';
    end if;
    when FY =>
    highway_yellow <= '0';
    highway_red <= '1';
    farm_yellow <= '1';
    farm_red <= '0';
    if (short = '1') then
                next_state <= HG;
                start_timer <= '1';
    else
            next_state <= FY;
            start_timer <= '0';
    end if;
    when others =>
    next_state <= "XX";
    start_timer <= 'X';
    highway_yellow <= 'X';
    highway_red <= 'X';
    farm_yellow <= 'X';
    farm_red <= 'X';
    end case;
    end if;
end process P2;
end imp;
```
