Language Design Issues

Syntax: how programs look

- Names and reserved words
- Instruction formats
- Grouping

Semantics: what programs mean

- Model of computation: sequential, concurrent
- Control and data flow
- Types and data representation

The Design of C

Taken from Dennis Ritchie's *C Reference Manual*

(Appendix A of Kernighan & Ritchie)

Lexical Conventions

Identifiers (words, e.g., `foo`, `printf`)

Sequence of letters, digits, and underscores, starting with a letter or underscore

Keywords (special words, e.g., `if`, `return`)

C has fairly few: only 23 keywords. Deliberate: leaves more room for users' names

Comments (between `/*` and `*/`)

Most fall into two basic styles: start/end sequences as in C, or until end-of-line as in Java's `//`

Lexical Conventions

C is a *free-form* language where whitespace mostly serves to separate tokens. Which of these are the same?

```
1+2           return this
1 + 2         returnthis
foo bar
foobar
```

Space is significant in some language. Python uses indentation for grouping, thus these are different:

```
if x < 3:           if x < 3:
    y = 2            y = 2
    z = 3            z = 3
```

What's in a Name?

In C, each name has a **storage class** (where it is) and a **type** (what it is).

Storage classes: Fundamental types: Derived types:

- | | | |
|--------------|------------------------|---------------|
| 1. automatic | 1. <code>char</code> | 1. arrays |
| 2. static | 2. <code>int</code> | 2. functions |
| 3. external | 3. <code>float</code> | 3. pointers |
| 4. register | 4. <code>double</code> | 4. structures |

Objects and lvalues

Object: area of memory

lvalue: refers to an object

An lvalue may appear on the left side of an assignment

```
a = 3; /* OK: a is an lvalue */
3 = a; /* 3 is not an lvalue */
```

Constants/Literals

Integers (e.g., 10)

Should a leading - be part of an integer or not?

Characters (e.g., `'a'`)

How do you represent non-printable or `'` characters?

Floating-point numbers (e.g., `3.5e-10`)

Usually fairly complex syntax, easy to get wrong.

Strings (e.g., `"Hello"`)

How do you include a `"` in a string?

Conversions

C defines certain automatic conversions:

- A `char` can be used as an `int`
- Floating-point arithmetic is always done with `doubles`; `floats` are automatically promoted
- `int` and `char` may be converted to `float` or `double` and back. Result is undefined if it could overflow.
- Adding an integer to a pointer gives a pointer
- Subtracting two pointers to objects of the same type produces an integer

Function definitions

```
type-specifier declarator ( parameter-list )
type-decl-list
{
    declaration-list
    statement-list
}
```

Example:

```
int max(a, b, c)
int a, b, c;
{
    int m;
    m = (a > b) ? a : b;
    return m > c ? m : c;
}
```

Scope Rules

Two types of scope in C:

1. Lexical scope

Essentially, place where you don't get "undeclared identifier" errors

2. Scope of external identifiers

When two identifiers in different files refer to the same object. E.g., a function defined in one file called from another.

The Preprocessor

Violates the free-form nature of C: preprocessor lines *must* begin with #.

Program text is passed through the preprocessor before entering the compiler proper.

Define replacement text:

```
# define identifier token-string
```

Replace a line with the contents of a file:

```
# include " filename "
```

More C trivia

The first C compilers did not check the number and type of function arguments.

The biggest change made when C was standardized was to require the type of function arguments to be defined:

Old-style	New-style
<pre>int f();</pre>	<pre>int f(int, int, double);</pre>
<pre>int f(a, b, c) int a, b; double c;</pre>	<pre>int f(int a, int b, double c) { }</pre>

Lexical Scope

Extends from declaration to terminating } or end-of-file.

```
int a;
int foo()
{
    int b;
    if (a == 0) {
        printf("A was 0");
        a = 1;
    }
    b = a; /* OK */
}
int bar()
{
    a = 3; /* OK */
    b = 2; /* Error: b out of scope */
}
```

C's Standard Libraries

<assert.h>	Generate runtime errors	assert(a > 0)
<ctype.h>	Character classes	isalpha(c)
<errno.h>	System error numbers	errno
<float.h>	Floating-point constants	FLT_MAX
<limits.h>	Integer constants	INT_MAX
<locale.h>	Internationalization	setlocale(...)
<math.h>	Math functions	sin(x)
<setjmp.h>	Non-local goto	setjmp(jb)
<signal.h>	Signal handling	signal(SIGINT,&f)
<stdarg.h>	Variable-length arguments	va_start(ap, st)
<stddef.h>	Some standard types	size_t
<stdio.h>	File I/O, printing.	printf("%d", i)
<stdlib.h>	Miscellaneous functions	malloc(1024)
<string.h>	String manipulation	strcmp(s1, s2)
<time.h>	Time, date calculations	localtime(tm)

Data Definitions

```
type-specifier init-declarator-list ;
```

```
declarator optional-initializer
```

Initializers may be constants or brace-enclosed, comma-separated constant expressions. Examples:

```
int a;

struct { int x; int y; } b = { 1, 2 };

float a, *b, c;
```

External Scope

<pre>file1.c: int foo() { return 0; }</pre>	<pre>file2.c: int baz() { foo(); /* Error */ }</pre>
<pre>int bar() { foo(); /* OK */ }</pre>	<pre>extern int foo(); int baff() { foo(); /* OK */ }</pre>

Language design

Language design is library design.

— Bjarne Stroustrup

Programs consist of pieces connected together.

Big challenge in language design: making it easy to put pieces together *correctly*. C examples:

- The function abstraction (local variables, etc.)
- Type checking of function arguments
- The #include directive
