I. INTRODUCTION

In this project, we aim to design a video game called Bastard Ice Cream. It's a one player game consists of the ice cream which controlled by the player and a fruit guard AI. The general purpose of the game is to eat up all the fruit in the map, meanwhile the player must avoid any physical touch which leads sprite dead with the fruit guard who will chases the player, the game will end if all the fruit are eaten up, or caught by the fruit guard.

II. SYSTEM ARCHITECTURE

Our project design is shown in the following block, which consists of CPU, SDRAM CONTROL, AUDIO CONTROL, VGACONTROL and PS2 CONTROL. Our project basically consists of three part of workload: VGA CONTROL, AUDIO CONTROL and software logic development.

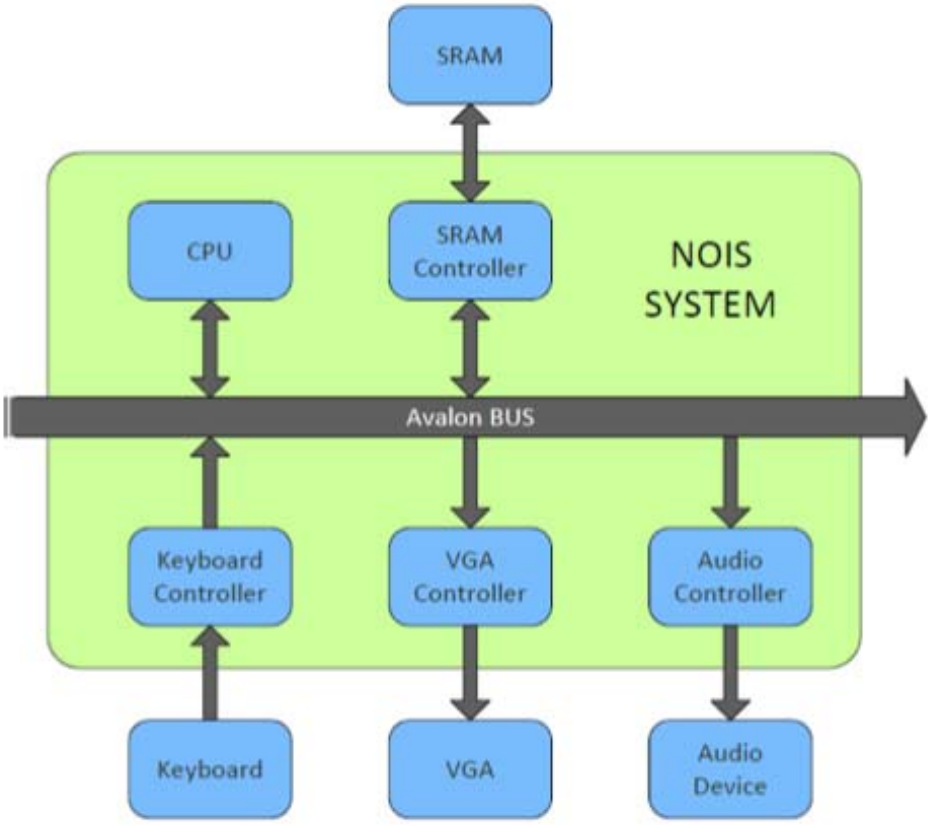

Figure 1: Implementation Architecture

III. VGA Display And Control

i) Game Image Abstraction & VGA Display

According to lab3 in the course, we noticed that we could use pictures on the Internet to feed into the FPGA and display the picture. According to the feature of the screen we are using, we divide our 640-480 pixels screen into tiles. Each 32-32 pixels construct one tile, so totally makes the screen a 20-15 tiles map.

To import characters and items of the game into our project, we use MATLAB to resize and abstract the figure data. The original figure is RGB 256*256*256 in color, but to save our memory, we use the high 5 bit of the color value which makes our color ranging from 32-256 for each.

Like VGA_R(9 downto 5) <= Sprite_R;

VGA_R(4 downto 0) <= “11111”;

This is really a high color range though.

Figure2-a: ice cream

Figure2-b: guard

To display the figure on the screen, we use three signal arrays to store the map information and according to that, our scanner (counter) on horizontal and vertical side could check whether it is inside certain tiles that need to display the corresponding items or sprites.

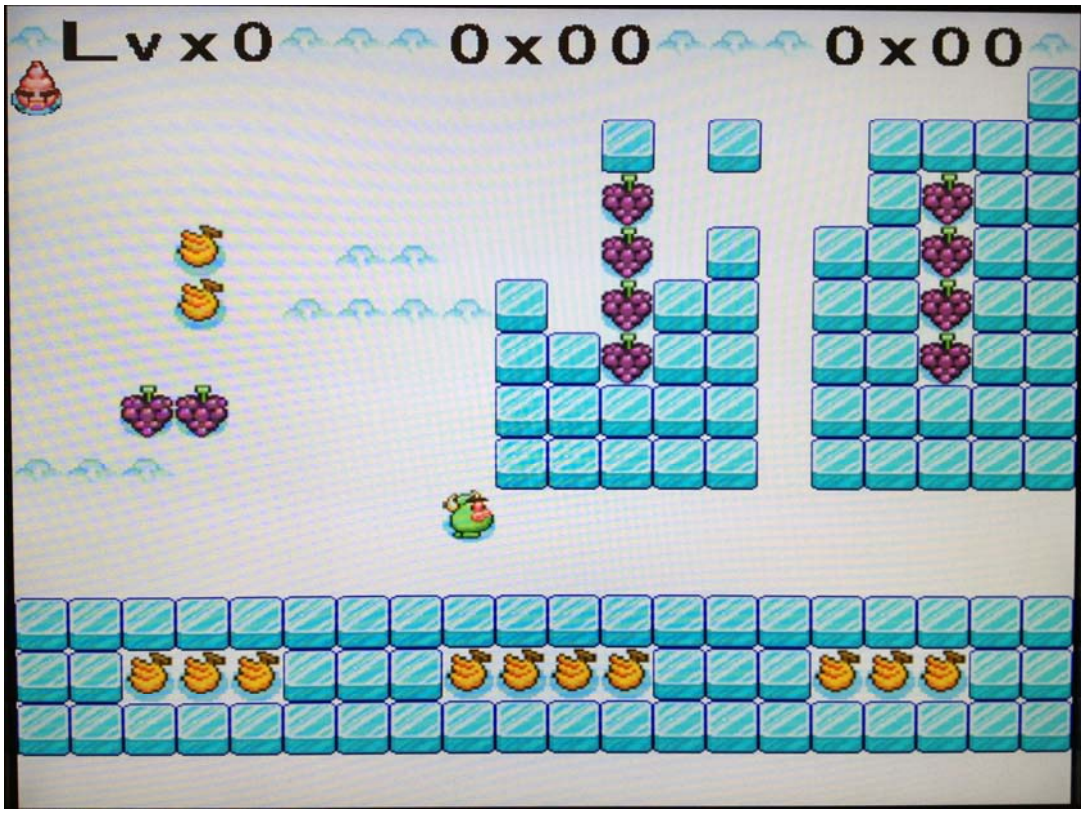

Figure3: real map

To display the under figure on the screen, we use a special number (like “00000”) to indicate that this pixel need to keep apparent for the under layer.

Difficulty & Improvement: Debugging with vhdl always consumes time, for mapping, we could make it into SDRAM or ROM to read from which will allow us to restart the game automatically. But as time limits, we didn’t achieve that point. On the other hand, I found a better solution for the picture to be shown is to change the value of the pixel on the screen when the scanner is on “BACK_PORCH” or “FRONT PORCH”, since we are not dealing with situation that the picture need to be changed all the time, this won’t affect much, but this is really a better way to do it. A pity is that we don’t really need to use such high resolution for RGB color because the original picture is really low resolution, this really affect the whole project after we finish all the picture abstraction, because our on chip memory is almost done with storing these pictures.

ii) Sprite Control & Animation

In this section, we need to use Nios-2(C) along with Quartus(vhdl) to control the select tile on the screen. In addition, keyboard need to be enabled.

To make our sprite controllable, we setup the keyboard, and use “W”,”S”,”A”,”D” keys to move the sprite ice cream “up”, ”left”, ”down”, ”right”. In software

development, we use a while loop to listen to the key information reported by hardware keyboard and react accordingly.

To introduce sprite animation shown on the screen, we need to import a large number of pictures of the sprite because every direction has three states when walking. The pictures are shown below. So in total 24 pictures are included.

Figure 4-a: motion of sprite going down

Figure 4-b: motion of guard going down

The picture are playing by hardware using vhdl to show them in order, each of them could be played for 4 pixel time. So for 32 pixels movement, the whole movement animation could be displayed for two times.

To store the data more efficient, we use ROM introduced in the slides to keep these picture data. To make the movement more real, we use pixel by pixel in the screen. But this could become a issue if we want to develop this function in software side. Unlike many games, our project has an artificial intelligence guard which need to be controlled by the program periodically. For example, player keeps pressing keyboard, in this case the guard could not move fluently.

To solve the above problem, we developed the movement of the sprite inside hardware, the software only need to give a direction, the hardware could then move pixel by pixel on the screen, after successful, it returns a signal to software. On the other hand, we set up the counter inside the hardware movement to make sure that the right state picture is selected. Finally we have this cartoon effect.

Difficulty & Improvement: This part is really tricky, because I have to separate the motion of the sprite from software to hardware. This comes up with several other problems when we are developing game logic.

IV. GAME LOGIC DEVELOPMENT

i). Sprite Skill & Level Selection

In this part, we enable the sprite with ability to generate and destroy ice tile, eat fruit. We generate three maps both in hardware and software so both hardware and software could check its own map other than transmitting a lot of data. We use unique numbers to map each kind of item on the screen. For the sake of generating and destroying ice tile, we use key “space ” to work. So once we detected an item, we check if it’s mapping value and process it accordingly.

After ice cream eats up all the fruit in one level, we will reset the position of the sprite and guard, and change the map to the next level.

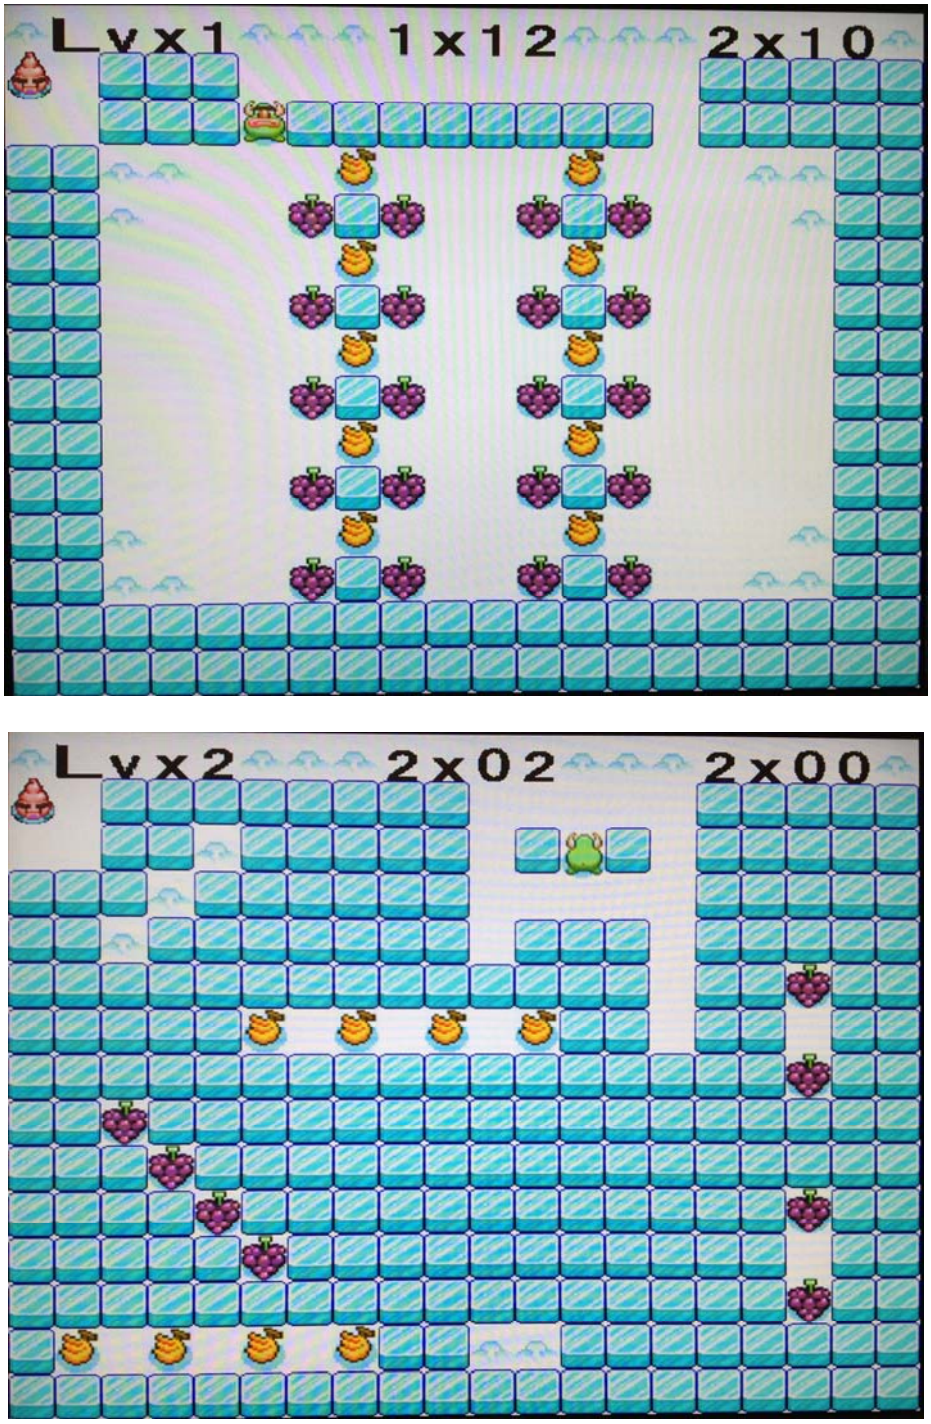

Figure 5: Level selection

If the ice cream eats up all the fruit for level 2, we will have a “WIN” character shown on the screen, otherwise a “LOSE” character will be shown.

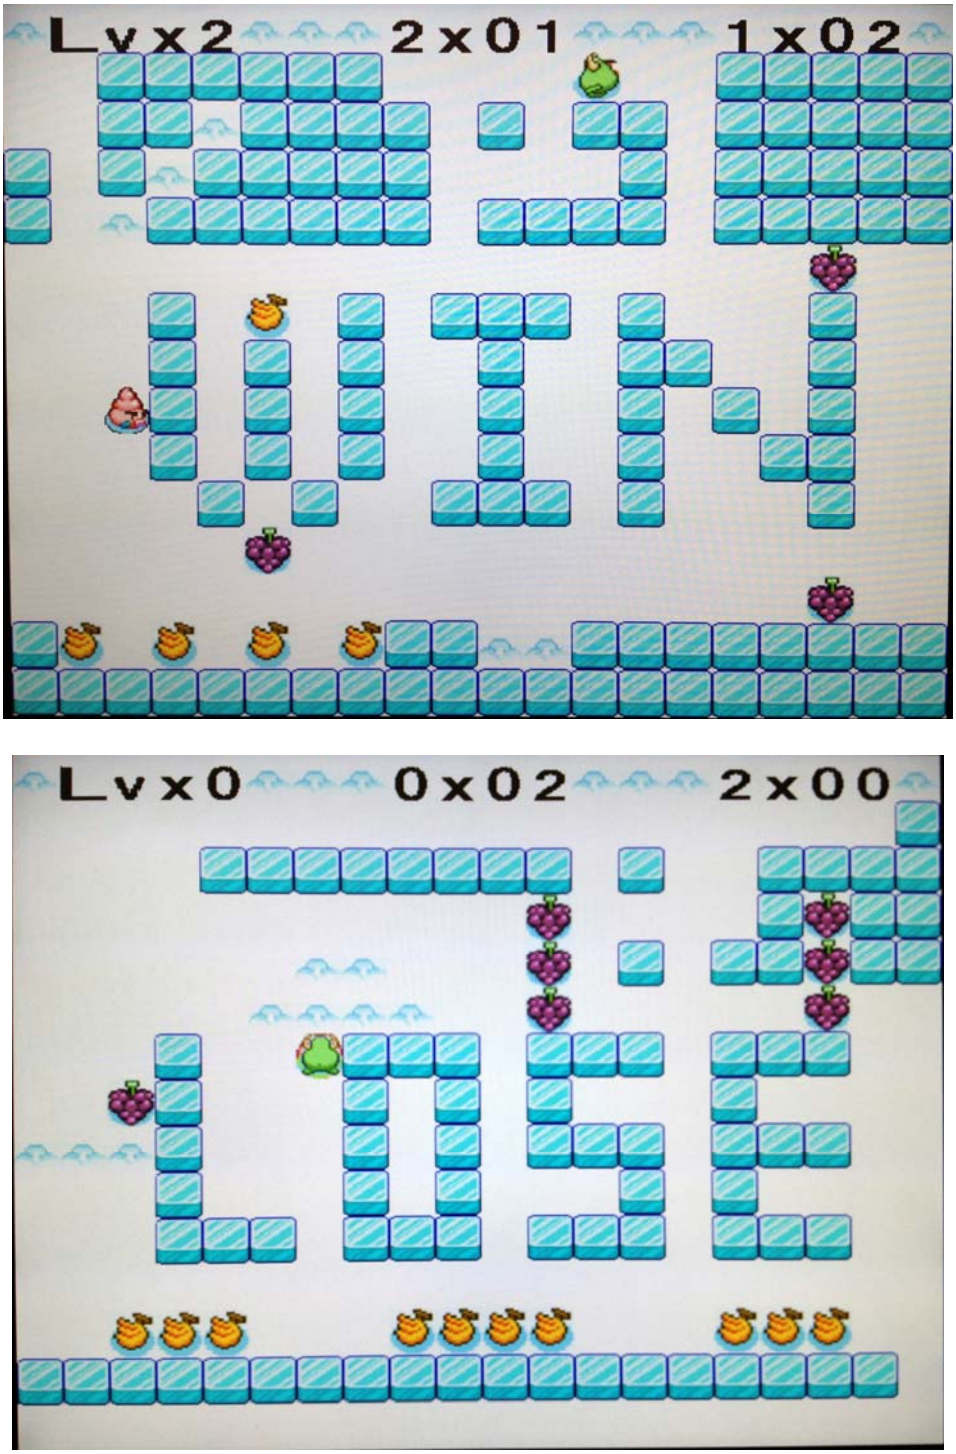

Figure 6: Win & lose Sign

Difficulty & Improvement: This part is a lot of work! The whole project depends on the logic part to integrate. When For debugging with this part, we face the problem with the actually position of the guard, the software doesn't know the exact pixel that the sprite is on, so we set up a guard lock, this ensure that the ice tile will not overlap with the guard sprite. On the other hand, if we have time, we could do the reset for the whole game, so we can start from the beginning.

ii). Artificial Intelligence Guard

The guard is implemented using interrupt. I developed two modes for guard: normal walk mode and chasing mode. I generate a random table for guard when it will walk like randomly to move around, it could also detect items that block it, the guard could eats ice, but will be blocked by fruit because it's protecting it. For the chasing mode, I developed the algorithm that the guard will chase the sprite. Moreover, it will speed up in this mode since I interacted with hardware so for animation and interrupt, both of them will become shorter which makes the guard moving very fast.

Difficulty & Improvement: The guard is the main reason that we couldn't make more fancy pictures in the game. I couldn't distribute more effort on the guard because there are many issues with logic part. To improve its performance, the guard can have more feature regarding different levels.

V. AUDIO IMPLEMENTATION

We have tried to implement our audio part in two different ways.

In our first approach, actually, we did similarly as the audio branch of lab 3. In the de2_wm8731_audio.vhd, we changed the step size of the sine wave sound, so that the frequency of the sine wave is changed, and different tones can be made. In another new higher-level file, we combined different frequencies of sound to make several sets of continuous music.

To connect with the video part of our project, we gave a number for each set of continuous music. The set of music with the number is called will be played. Theoretically, there could be 2n sets of continuous music can be produced. And for each set, there should be 2n tones combined. The factors that limit the length and diversity of this kind of music are memory and compilation time. In addition, to make it sound perfectly, we calculated the several counters in the de2_wm8731_audio.vhd, for example, "lrck", to change them to achieve rigorous frequencies, which are 262Hz, 294Hz, 330Hz, 349Hz, 392Hz, 440Hz and 493Hz. However, as the adjustment is a little complicated, we haven't made all these seven tones achieved together. This is the main reason why we didn't finally follow this approach.

Another implementation method follows this schema: we download sounds that we desire directly, instead of composing them on our own. Then we use a MATLAB to resample this wav file, by writing a script that enables generating a respective txt file containing the resampled wav represented by a sequence of hex numbers. To implement this wav sound into the VHDL code, we modified the de_wm8731_audio.vhd from lab3 to store the hex sequence in a ROM (say ROM1), which will later be assigned to sin_out, with a variable called "num" works as the controller in selecting this ROM. By the same way of implementation, we can assign

different sound effects as separate sequences of hex numbers to ROM2, ROM3, etc. The value of num is assigned from writedata, which is controlled from the nios_system via SOPC. Therefore, by setting the proper logical control, we enable sound effects when certain actions are triggered.

Difficulties and improvements: Although Lab3 has provided a way in sound creation, which we originally decided to follow, we implemented our sound effects via the second method at the end. We do have designed to generate sound effects by composing different tunes manually, but we found it very demanding in setting the precise pitch. The cost in doing this other than composing manually is that we sacrificed a little on the purity of the sound effect, i.e. some distortion exists in the final output. This actually depends a lot on the MATLAB resample rate, if we increase the rate, there will be less distortions; however, ths will result in increment on the data scale of the hex sequence, which will finally result in increment in memory usage, in considering this tradeoff, we reached an balance in setting the resample frequency to 2900Hz.

VI. CONCLUSION

In our project, we truly learned how to use vhdl which is not familiar to us at all previously. Only after we change the architecture several times do we recognize that the design and architecture is the soul of the whole project, some tiny errors or ambiguous in the design at the beginning would lead to tons of changes later. We also have a clearer vision about how to program from a hardware perspective to achieve functionality. Things need to be done in software are from instruction by instruction when only have one CPU, but hardware as state machine could really do them in parallel, they are purely different.

APPENDIX: WORK DISTRIBUTION

i) VGA Display And Control
   - Image Abstraction & VGA Display: Haodan Huang, Lei Mao, Yaozhong Song
   - Sprite Control & Animation: Haodan Huang

ii) Game Logic Development
   - Sprite Skill & Level Selection: Ziheng Zhou, Haodan Huang
   - Artificial Intelligence: Haodan Huang

iii) Audio Implementation
   - Sound abstraction and generation: Lei Mao Yaozhong Song
   - Integrate with video part: Ziheng Zhou, Yaozhong Song, Lei Mao
