Figure 3: C program and its representation comprising three hyperblocks; each hyperblock is shown as a numbered rectangle. The dotted lines represent predicate values. (This figure omits the token edges used for memory synchronization.)

Figure 8: Memory access network and implementation of the value and token forwarding network. The LOAD produces a data value consumed by the oval node. The STORE node may depend on the load (i.e., we have a token edge between the LOAD and the STORE, shown as a dashed line). The token travels to the root of the tree, which is a load-store queue (LSQ).

#### The Lesson of Logic Synthesis: the Enabling Technology

How do you compile and optimize a digital logic circuit?

$$f_{1} = abcd + abce + a\overline{b}c\overline{d} + a\overline{b}\overline{c}\overline{d} + \overline{a}c + cdf + ab\overline{c}\overline{d}\overline{e} + a\overline{b}\overline{c}d\overline{f}$$

$$f_1 = c(x + \overline{a}) + a\overline{cx}$$
  

$$f_2 = gx$$
  

$$x = d(b + f) + \overline{d}(\overline{b} + e)$$

#### The Lesson of Logic Synthesis: the Enabling Technology

How do you compile and optimize a digital logic circuit? Use a simple, formal model and automate it.

$$\begin{aligned} f_1 &= abcd + abce + a\overline{b}c\overline{d} + a\overline{b}\overline{c}\overline{d} + \overline{a}c + cdf + ab\overline{c}\overline{d}\overline{e} + a\overline{b}\overline{c}d\overline{f} \\ f_2 &= bdg + \overline{b}dfg + \overline{b}dg + b\overline{d}eg \\ & \text{Minimize} \end{aligned}$$

$$f_{1} = bcd + bce + \overline{bd} + \overline{a}c + cdf + ab\overline{c}\overline{d}\overline{e} + a\overline{b}\overline{c}d\overline{f}$$
  
$$f_{2} = bdg + dfg + \overline{bd}g + \overline{d}eg$$

Factor

$$f_1 = c \left( b(d+e) + \overline{b}(\overline{d}+f) + \overline{a} \right) + a\overline{c}(b\overline{d}\overline{e} + \overline{b}d\overline{f})$$
  
$$f_2 = g \left( d(b+f) + \overline{d}(\overline{b}+e) \right)$$

Decompose

$$f_1 = c(x + \overline{a}) + a\overline{cx}$$
  

$$f_2 = gx$$
  

$$x = d(b + f) + \overline{d}(\overline{b} + e)$$

## The High-Level Synthesis Lessons

#### Don't Start From C

"The so-called high-level specifications in reality grew out of the need for simulation and were often little more than an input language to make a discrete event simulator reproduce a specific behavior."

Gupta and Brewer, High-Level Synthesis: A Retrospective, 2008.

#### **Don't Forget Memory**

Goldstein et al.'s Phoenix synthesized asychronous hardware from ANSI C. Required heroic work [CGO 2003] to recover any parallelism.

#### Our Approach

#### **Our Approach**

▲□▶▲□▶▲□▶▲□▶ ■ のへで

#### **Our Approach**

# Why Functional Specifications?

- Referential transparency/side-effect freedom make formal reasoning about programs vastly easier
- Inherently concurrent and race-free (Thank Church and Rosser). If you want races and deadlocks, you need to add constructs.
- Immutable data structures makes it vastly easier to reason about memory in the presence of concurrency

# Why FPGAs?

- We do not know the structure of future memory systems Homogeneous/Heterogeneous? Levels of Hierarchy? Communication Mechanisms?
- We do not know the architecture of future multi-cores Programmable in Assembly/C? Single- or multi-threaded?

Use FPGAs as a surrogate. Ultimately too flexible, but representative of the long-term solution.

## Fibonacci Datapath

## Implementing the Stack in Hardware

#### This uses a stack data type that looks like a kind of list: **data** Stack = Fib2 Int Stack | Fib3 Int Stack | Fib0

A naïve, but correct, way to implement it in hardware:

▲□▶▲□▶▲□▶▲□▶ □ のQ@

Fib3 42 (Fib2 17 (Fib3 8 (Fib3 2 Fib0)))

▲□▶▲□▶▲□▶▲□▶ ■ のへで

Fib3 42 (Fib2 17 (Fib3 8 (Fib3 2 Fib0)))

The only "pop" operation discards the previous top-of-stack f (Cont (Fib3 n1 c) n2) = f (Cont c (n1 + n2))

so this code will never generate a tree. Sequential memory allocation is safe.

Fib3 42 (Fib2 17 (Fib3 8 (Fib3 2 Fib0)))

Sequential memory allocation makes "next" pointers predictable ...

▲□▶▲□▶▲□▶▲□▶ □ のQ@

Fib3 42 (Fib2 17 (Fib3 8 (Fib3 2 Fib0)))

...so there is no need to store them.

Constructor (Fib0) always returns 0.

Constructors (Fib2/3 n s) writes (Fib2/3 n) at s + 1 and returns s + 1.

< ロ ト < 同 ト < 三 ト < 三 ト < 三 ・ の Q (P)</p>

Reading 0 returns Fib0; reading *s* returns (Fib2/3 n s - 1).

# Specializing Data Types

Stacks are the tip of the iceberg

Synthesizing custom memory systems for specific types is a key goal of this project

Shape Analysis relevant here

This is a simple case; a simple, mathematical IR enables such clever optimizations.

#### Unrolling Code for Better Parallelism

 $\begin{array}{l} fib \ 0 = 0 \\ fib \ 1 = 1 \\ fib \ n = fib \ (n-1) + fib \ (n-2) \end{array}$ 

*fib* (n-1) and *fib* (n-2) are functionally independent.

Yet because they share *fib*, they are performed sequentially.

## Unrolling Code for Better Parallelism

 $fib \ 0 = 0$   $fib \ 1 = 1$   $fib \ n = fib' \ (n-1) + fib'' \ (n-2)$   $fib' \ 0 = 0$   $fib' \ 1 = 1$   $fib'' \ 0 = 0$   $fib'' \ 1 = 1$   $fib'' \ 0 = 0$   $fib'' \ 1 = 1$  $fib'' \ n = fib'' \ (n-1) + fib'' \ (n-2)$ 

By unrolling the recursion once, *fib*' and *fib*'' run in parallel.

Unrolling Types for Better Locality

data Stack = Fib2 Int Stack | Fib3 Int Stack | Fib0

Each Stack object naturally represents a single activation record

Unrolling Types for Better Locality

data Stack = Fib2 Int Stack' | Fib3 Int Stack' | Fib0

data Stack' = Fib2 Int Stack'' | Fib3 Int Stack'' | Fib0

data Stack'' = Fib2 Int Stack''' | Fib3 Int Stack''' | Fib0

data Stack''' = Fib2 Int Stack | Fib3 Int Stack | Fib0 A similar unrolling amounts to packing records that can be processed in parallel

Abstract data types enables this

Imagine trying to do this safely in a C compiler

< ロ ト < 同 ト < 三 ト < 三 ト < 三 ・ の Q (P)</p>

Example: Huffman Decoder in Haskell

data HTree = Branch HTree HTree | Leaf Char

decode :: HTree -> [Bool] -> [Char] -- Huffman tree & bitstream to symbols

decode table str = decoder table str
where
 decoder (Leaf s) i = s : (decoder table i) -- Identified symbol; start again
 decoder\_[] = []
 decoder (Branch f\_) (False:xs) = decoder f xs -- 0: follow left branch
 decoder (Branch\_t) (True:xs) = decoder t xs -- 1: follow right branch

< 日 > < 同 > < 目 > < 目 > < 目 > < 回 > < ○ < ○ </li>

Three data types: Input bitstream, output character stream, and Huffman tree
