5 Discrete central limit theorems [Chen-Goldstein-Shao] – computational learning theory.

Why is central limit theorem useful?

Central limit theorem: Even if X_1, \ldots, X_n are unwieldy random variables, their sum $X_1 + \ldots + X_n$ is *nice*.

◆□▶ ◆□▶ ◆臣▶ ◆臣▶ □臣 ○のへ⊙

Why is central limit theorem useful?

Central limit theorem: Even if X_1, \ldots, X_n are unwieldy random variables, their sum $X_1 + \ldots + X_n$ is *nice*.

In some applications, the precise convergence to the Gaussian distribution is important.

In others, the fact that a Gaussian can be parameterized by two parameters is sufficient.

Berry-Esséen theorem

Theorem

Let $X_1, ..., X_n$ be n independent centered random variables such that $Var(X_i) = \sigma_i^2$ and $\mathbf{E}[|X_i|^3] = \beta_{3,i}$. Define $S = \sum X_i$, $\sigma^2 = Var(S)$ and $\beta_3 = \sum \beta_{3,i}$. Then,

$$d_{\mathcal{K}}(S,\mathcal{N}(0,\sigma^2))=O(1)\cdot rac{eta_3}{\sigma^3}.$$

$$d_{\mathcal{K}}(X,Y) = \sup_{z \in \mathbb{R}} \big| \Pr[X \leq z] - \Pr[Y \leq z] \big|.$$

▲□▶ ▲□▶ ▲□▶ ▲□▶ ■ ● ●

Corollary of the Berry-Esséen theorem

Corollary

Let $X_1, ..., X_n$ be n independent identical centered random variables such that $Var(X_i) = \sigma_*^2$ and $\mathbf{E}[|X_i|^3] = \beta_{3,*}$ (for all $1 \le i \le n$). Define $S = \sum_i X_i$. Then,

$$d_{\mathcal{K}}(S,\mathcal{N}(0,n\sigma_*^2))=O\left(\frac{1}{\sqrt{n}}\right)\cdot\frac{\beta_{3,*}}{\sigma_*^3}.$$

▲□▶ ▲□▶ ▲□▶ ▲□▶ □ のQで

Corollary of the Berry-Esséen theorem

Let us assume that the random variable X_i is *hypercontractive* – in other words, there is a constant C > 0 such that

 $\mathbf{E}[|X_i|^3] \leq C \cdot \left(\mathbf{E}[|X_i|^2]\right)^{3/2}.$

Corollary of the Berry-Esséen theorem

Let us assume that the random variable X_i is hypercontractive – in other words, there is a constant C > 0 such that

$$\mathbf{E}[|X_i|^3] \leq C \cdot \left(\mathbf{E}[|X_i|^2]\right)^{3/2}.$$

This implies that $\beta_{3,*}/\sigma_*^3 \leq C$. Thus, the error term in Berry-Esséen theorem is now

$$d_{\mathcal{K}}(S,\mathcal{N}(0,n\sigma_*^2))=O\bigg(\frac{C}{\sqrt{n}}\bigg).$$

Berry-Esséen for non identical random variables

Continue to assume that X_1, \ldots, X_n are all *C*-hypercontractive.

Suppose
$$\max_i \sigma_i^2 \leq \epsilon^2 \cdot (\sum_{j=1}^n \sigma_j^2).$$

Then, the error term in Berry-Esséen becomes

$$\frac{\beta_3}{\sigma^3} \leq C \cdot \frac{\sum_j \sigma_j^3}{(\sum_j \sigma_j^2)^{1.5}} \leq C \cdot \epsilon.$$

◆□▶ ◆□▶ ◆臣▶ ◆臣▶ □臣 ○のへ⊙

Berry-Esséen for non identical random variables

Continue to assume that X_1, \ldots, X_n are all *C*-hypercontractive.

Suppose
$$\max_i \sigma_i^2 \leq \epsilon^2 \cdot (\sum_{j=1}^n \sigma_j^2).$$

Then, the error term in Berry-Esséen becomes

$$\frac{\beta_3}{\sigma^3} \leq C \cdot \frac{\sum_j \sigma_j^3}{(\sum_j \sigma_j^2)^{1.5}} \leq C \cdot \epsilon.$$

Thus, as long as none of the individual variances are too large, the sum $\sum X_i$ converges to a Gaussian.

How do you prove Berry-Esséen?

There are many known techniques used to prove "central limit theorems".

▲□▶ ▲□▶ ▲ 三▶ ▲ 三▶ 三三 - のへぐ

How do you prove Berry-Esséen?

There are many known techniques used to prove "central limit theorems".

- 1. Lindeberg exchange method (hybrid method) used by MOO in their proof of the invariance principle.
- 2. Stein's method based on constructing an operator of which the Gaussian is a fixed point.
- Characteristic functions aka Fourier analysis, the original method of Esséen.

We will only prove (at a high level) this for i.i.d. random variables.

Assume that X_1, \ldots, X_n are i.i.d. with common distribution **X**. Further, $\mathbf{E}[\mathbf{X}] = 0$, $\mathbf{E}[\mathbf{X}^2] = 1$ and $\mathbf{E}[\mathbf{X}^4] \le 10$. In fact, for simplicity, assume that all the moments of **X** exist.

Goal: Show that $\mathbf{S} = \frac{X_1 + \dots + X_n}{\sqrt{n}}$ satisfies

$$d_{\mathcal{K}}(S,\mathcal{N}(0,1))=O\bigg(\frac{1}{\sqrt{n}}\bigg).$$

Strategy to prove the Berry-Eséeen theorem

Approximate Fourier inversion

$$\Pr[\mathbf{S} \le x] - \Pr[\mathbf{Z} \le x] \le \frac{1}{2\pi} \int_{\xi=-\tau}^{\xi=\tau} \frac{|\widehat{\mathbf{S}}(\xi) - \widehat{\mathbf{Z}}(\xi)|}{|\xi|} d\xi + O\left(\frac{1}{\tau}\right).$$

Choose $T \approx \sqrt{n}$. We will bound $|\widehat{\mathbf{S}}(\xi) - \widehat{\mathbf{Z}}(\xi)|$ for $|\xi| \leq T$.

Showing $\widehat{\mathbf{S}}(\xi)$ is close to $\widehat{\mathbf{Z}}(\xi)$

Let us start with $\widehat{\mathbf{Z}}(\xi)$. Recall $\mathbf{Z} = \mathcal{N}(0, 1)$. It easily follows that

$$\widehat{\mathsf{Z}}(\xi) = \int_{x} \frac{1}{\sqrt{2\pi}} e^{-\frac{x^2}{2}} e^{i\xi x} dx = e^{-\frac{\xi^2}{2}}.$$

Showing $\widehat{\mathbf{S}}(\xi)$ is close to $\widehat{\mathbf{Z}}(\xi)$

Let us start with $\widehat{\mathbf{Z}}(\xi)$. Recall $\mathbf{Z} = \mathcal{N}(0,1)$. It easily follows that

$$\widehat{\mathsf{Z}}(\xi) = \int_{x} \frac{1}{\sqrt{2\pi}} e^{-\frac{x^2}{2}} e^{i\xi x} dx = e^{-\frac{\xi^2}{2}}.$$

On the other hand,

$$\widehat{\mathbf{S}}(\xi) = (\widehat{\mathbf{X}}(\xi/\sqrt{n}))^n = \left(1 + \sum_{j=1}^{\infty} \frac{\mathbf{i}^j \cdot \mathbf{E}[\mathbf{X}^j]}{j!} \frac{\xi^j}{n^{j/2}}\right)^n$$
$$\widehat{\mathbf{S}}(\xi) = \left(1 - \frac{\xi^2}{2n} + o(|\xi|^2/n)\right)^n.$$

▲□▶ ▲□▶ ▲ 三▶ ▲ 三▶ 三 のへぐ

Showing $\widehat{\mathbf{S}}(\xi)$ is close to $\widehat{\mathbf{Z}}(\xi)$

Note: Taylor expansion of $\widehat{\mathbf{X}}(\xi/\sqrt{n})$ is valid only if $|\xi|$ is small.

Claim: For $|\xi| \leq \frac{\sqrt{n}}{100}$, we have

$$\left|\widehat{\mathsf{S}}(\xi)-\widehat{\mathsf{Z}}(\xi)
ight|=Oigg(rac{1}{\sqrt{n}}|\xi|^3e^{-\xi^2/3}igg).$$

Note: Taylor expansion of $\widehat{\mathbf{X}}(\xi/\sqrt{n})$ is valid only if $|\xi|$ is small.

Claim: For $|\xi| \leq \frac{\sqrt{n}}{100}$, we have

$$ig|\widehat{\mathsf{S}}(\xi) - \widehat{\mathsf{Z}}(\xi)ig| = Oigg(rac{1}{\sqrt{n}}|\xi|^3e^{-\xi^2/3}igg).$$

Plugging this back into approximate Fourier inversion (with $T = \sqrt{n}/100$),

$$\Pr[\mathbf{S} \le x] - \Pr[\mathbf{Z} \le x] \le \frac{1}{2\pi} \int_{\xi=-T}^{\xi=T} \frac{|\xi|^2 e^{-\xi^2/3}}{\sqrt{n}} d\xi + O\left(\frac{1}{T}\right).$$

Note: Taylor expansion of $\widehat{\mathbf{X}}(\xi/\sqrt{n})$ is valid only if $|\xi|$ is small.

Claim: For $|\xi| \leq \frac{\sqrt{n}}{100}$, we have

$$ig| \widehat{\mathbf{\mathsf{S}}}(\xi) - \widehat{\mathbf{\mathsf{Z}}}(\xi) ig| = Oigg(rac{1}{\sqrt{n}} |\xi|^3 e^{-\xi^2/3}igg).$$

Note: Taylor expansion of $\widehat{\mathbf{X}}(\xi/\sqrt{n})$ is valid only if $|\xi|$ is small.

Claim: For $|\xi| \leq \frac{\sqrt{n}}{100}$, we have

$$\widehat{\mathsf{S}}(\xi) - \widehat{\mathsf{Z}}(\xi) \Big| = O \bigg(rac{1}{\sqrt{n}} |\xi|^3 e^{-\xi^2/3} \bigg).$$

Proof technique: Split $|\xi|$ into the high $|\xi|$ regime and the low $|\xi|$ regime. In particular, define

$$\Gamma_{\mathsf{low}} = \{\xi : |\xi| \le n^{\frac{1}{6}}\} \text{ and } \Gamma_{\mathsf{high}} = \{\xi : n^{\frac{1}{2}}/100 \ge |\xi| > n^{\frac{1}{6}}\}.$$

Note: Taylor expansion of $\widehat{\mathbf{X}}(\xi/\sqrt{n})$ is valid only if $|\xi|$ is small.

Claim: For $|\xi| \leq \frac{\sqrt{n}}{100}$, we have

$$ig| \widehat{\mathbf{\mathsf{S}}}(\xi) - \widehat{\mathbf{\mathsf{Z}}}(\xi) ig| = Oigg(rac{1}{\sqrt{n}} |\xi|^3 e^{-\xi^2/3}igg).$$

Note: Taylor expansion of $\widehat{\mathbf{X}}(\xi/\sqrt{n})$ is valid only if $|\xi|$ is small.

Claim: For $|\xi| \leq \frac{\sqrt{n}}{100}$, we have

$$\widehat{\mathsf{S}}(\xi) - \widehat{\mathsf{Z}}(\xi) \Big| = O \bigg(rac{1}{\sqrt{n}} |\xi|^3 e^{-\xi^2/3} \bigg).$$

Proof technique: When $\xi \in \Gamma_{low}$, then we apply Taylor's expansion – recall

$$\widehat{\mathbf{S}}(\xi) = \left(1 - rac{\xi^2}{2n} + o(|\xi|^2/n)
ight)^n.$$

Note: Taylor expansion of $\widehat{\mathbf{X}}(\xi/\sqrt{n})$ is valid only if $|\xi|$ is small.

Claim: For $|\xi| \leq \frac{\sqrt{n}}{100}$, we have

$$ig| \widehat{\mathbf{\mathsf{S}}}(\xi) - \widehat{\mathbf{\mathsf{Z}}}(\xi) ig| = Oigg(rac{1}{\sqrt{n}} |\xi|^3 e^{-\xi^2/3}igg).$$

Note: Taylor expansion of $\widehat{\mathbf{X}}(\xi/\sqrt{n})$ is valid only if $|\xi|$ is small.

Claim: For $|\xi| \leq \frac{\sqrt{n}}{100}$, we have

$$\widehat{\mathbf{S}}(\xi) - \widehat{\mathbf{Z}}(\xi) \Big| = O\left(rac{1}{\sqrt{n}}|\xi|^3 e^{-\xi^2/3}
ight).$$

Proof technique: On the other hand, it is not difficult to show that $|\widehat{\mathbf{S}}(\xi)| \leq e^{-\frac{2\xi^2}{3}}$. Using the fact that $|\widehat{\mathbf{Z}}(\xi)| = e^{-\frac{\xi^2}{2}}$. When $\xi \in \Gamma_{\text{high}}$, this is enough

Finishing the proof of Berry-Esséen

For all $|\xi| \leq \frac{\sqrt{n}}{100}$, we have $\left|\widehat{\mathbf{S}}(\xi) - \widehat{\mathbf{Z}}(\xi)\right| = O\left(\frac{1}{\sqrt{n}}|\xi|^3 e^{-\xi^2/3}\right).$

Finishing the proof of Berry-Esséen

For all $|\xi| \leq \frac{\sqrt{n}}{100}$, we have

$$\left|\widehat{\mathbf{S}}(\xi) - \widehat{\mathbf{Z}}(\xi)\right| = O\left(rac{1}{\sqrt{n}}|\xi|^3 e^{-\xi^2/3}
ight).$$

Plugging this back into the approximate Fourier inversion formula (which is)

$$|\Pr[\mathbf{S} \le x] - \Pr[\mathbf{Z} \le x]| \le \frac{1}{2\pi} \int_{\xi=-T}^{\xi=T} \frac{|\widehat{\mathbf{S}}(\xi) - \widehat{\mathbf{Z}}(\xi)|}{|\xi|} d\xi + O\left(\frac{1}{T}\right),$$

we get $\Pr[\mathbf{S} \leq x] - \Pr[\mathbf{Z} \leq x]| = O(n^{-1/2}).$

Application of the Berry-Esséen theorem

Stochastic knapsack

Suppose you have *n* items, each with a profit c_i and a stochastic weight X_i where each X_i is a positive valued random variable.

▲□▶ ▲□▶ ▲□▶ ▲□▶ ▲□ ● ● ●

Application of the Berry-Esséen theorem

Stochastic knapsack

Suppose you have *n* items, each with a profit c_i and a stochastic weight X_i where each X_i is a positive valued random variable.

Goal: Given a knapsack with capacity θ and error tolerance probability p, pack a subset S of items such that

$$\Pr[\sum_{j\in S} \mathbf{X}_j \leq \theta] \geq 1 - p,$$

so that the *profit* $\sum_{j \in S} c_j$ is maximized.

Berry-Esséen theorem for stochastic knapsack

Stochastic knapsack

Suppose you have *n* items, each with a profit c_i and a stochastic weight X_i where each X_i is of the form

$$\mathbf{X}_{i} = \begin{cases} w_{\ell,i} & \text{w.p. } \frac{1}{2} \\ w_{h,i} & \text{w.p. } \frac{1}{2} \end{cases}$$

Here all $w_{\ell,i} \in [1, \ldots, M/4]$ and $w_{h,i} \in [3M/4, \ldots, M]$ where M = poly(n). Further, all profits $c_i \in [1, \ldots, M]$.

Algorithmic result for stochastic knapsack

Result: There is an algorithm which for any error parameter $\epsilon > 0$, runs in time poly $(M, n^{1/\epsilon^2})$ and outputs a set S_{*} such that

$$\Pr[\sum_{j \in S_*} \mathbf{X}_j \le \theta] \ge 1 - p - \epsilon,$$

▲□▶ ▲□▶ ▲□▶ ▲□▶ ▲□ ● ● ●

such that $\sum_{j \in S_*} c_j = \mathsf{OPT}$.

$$\mathsf{E}[|\mathbf{Y}_i|^3] \leq \left(\mathsf{E}[|\mathbf{Y}_i|^2]\right)^{3/2}.$$

▲□▶▲□▶▲≡▶▲≡▶ ≡ めぬぐ

Thus, we can potentially apply Berry-Esséen to a sum of X_i .

Main idea behind the algorithm

Observation I: If we "center" random variable X_i , i.e, $Y_i = X_i - E[X_i]$, then it satisfies

$$\mathsf{E}[|\mathsf{Y}_i|^3] \leq \left(\mathsf{E}[|\mathsf{Y}_i|^2]\right)^{3/2}.$$

Thus, we can potentially apply Berry-Esséen to a sum of X_i .

Observation II: Consider any subset of items S with $|S| \ge 100/\epsilon^2$. Then,

$$\max_{i} \operatorname{Var}(\mathbf{X}_{i}) \leq \epsilon^{2} \cdot (\sum_{j \in S} \operatorname{Var}(\mathbf{X}_{j})).$$

▲□▶ ▲□▶ ▲□▶ ▲□▶ ▲□ ● ● ●

Step 1: Either the optimum solution S_{opt} is such that $|S_{\text{opt}}| \leq 100/\epsilon^2$. In this case, we can *brute-force* search for S_{opt} . Running time is $n^{\Theta(1/\epsilon^2)}$.

▲□▶ ▲□▶ ▲□▶ ▲□▶ ▲□ ● ● ●

Step 1: Either the optimum solution S_{opt} is such that $|S_{opt}| \leq 100/\epsilon^2$. In this case, we can *brute-force* search for S_{opt} . Running time is $n^{\Theta(1/\epsilon^2)}$.

Step 2: Otherwise, $|S_{opt}| > 100/\epsilon^2$. In this case, define μ_{opt} , σ_{opt}^2 and C_{opt} as (i) $\mu_{opt} = \sum_{j \in S_{opt}} \mathbf{E}[\mathbf{X}_j]$; (ii) $\sigma_{opt}^2 = \sum_{j \in S_{opt}} Var(\mathbf{X}_j)$; (iii) $C_{opt} = \sum_{j \in S_{opt}} c_j$.

Observe that μ_{opt} , σ_{opt}^2 and C_{opt} are all integral multiples of 1/4 bounded by M^2 .

◆□▶ ◆□▶ ◆臣▶ ◆臣▶ □臣 ○のへ⊙

Observe that μ_{opt} , σ_{opt}^2 and C_{opt} are all integral multiples of 1/4 bounded by M^2 .

We use dynamic programming to find S_* such that $C_{opt} = C_*$, $\mu_{opt} = \mu_*$ and $\sigma_{opt}^2 = \sigma_*^2$.

Observe that μ_{opt} , σ_{opt}^2 and C_{opt} are all integral multiples of 1/4 bounded by M^2 .

We use dynamic programming to find S_* such that $C_{opt} = C_*$, $\mu_{opt} = \mu_*$ and $\sigma_{opt}^2 = \sigma_*^2$.

Consequence of Berry-Esséen theorem:

$$\Pr[\sum_{j \in S_*} \mathbf{X}_j \le \theta] \ge \Pr[\sum_{j \in S_{\text{opt}}} \mathbf{X}_j \le \theta] - \epsilon.$$

Consequence of Berry-Esséen theorem:

$$\Pr[\sum_{j \in S_*} \mathbf{X}_j \le \theta] \ge \Pr[\sum_{j \in S_{\text{opt}}} \mathbf{X}_j \le \theta] - \epsilon.$$

This is because by Berry-Esséen, the distribution of $\sum_{j \in S_*} X_j$ and $\sum_{j \in S_{opt}} X_j$ follows essentially Gaussian (and their means and variances match).

General algorithmic result for stochastic optimization

Suppose the item sizes $\{\mathbf{X}_i\}_{i=1}^n$ are all hypercontractive – i.e., $\mathbf{E}[|\mathbf{X}_i|^3] \leq O(1) \cdot (\mathbf{E}[|\mathbf{X}_i|^2])^{3/2}$.

General algorithmic result for stochastic optimization

Suppose the item sizes $\{\mathbf{X}_i\}_{i=1}^n$ are all hypercontractive – i.e., $\mathbf{E}[|\mathbf{X}_i|^3] \leq O(1) \cdot (\mathbf{E}[|\mathbf{X}_i|^2])^{3/2}$.

Theorem: When item sizes are hypercontractive, then there is an algorithm running in time $n^{O(1/\epsilon^2)}$ such that the output set S_* satisfies

1.
$$\sum_{j \in S_*} c_j \ge (1 - \epsilon) \cdot (\sum_{j \in S_{opt}} c_j).$$

2. $\Pr[\sum_{j \in S_*} \mathbf{X}_j \le \theta] \ge \Pr[\sum_{j \in S_{opt}} \mathbf{X}_j \le \theta] - \epsilon.$

where $\ell(x)$ is a linear form and $\lambda = \mathbf{E}[p(x) \cdot \ell^2(x)]$. If λ is large, then p(x) is very far from a Gaussian.

Central limit theorem for quadratic polynomials

Theorem

Let $p(x) : \mathbb{R}^n \to \mathbb{R}$ such that Var(p(x)) = 1 and $\mathbf{E}[p(x)] = \mu$. Express $p(x) = x^T A x + \langle b, x \rangle + c$ where $A \in \mathbb{R}^{n \times n}$ and $b \in \mathbb{R}^n$. Let $\|A\|_{op} \le \epsilon$ and $\|b\|_{\infty} \le \epsilon$. Suppose, $\mathbf{x} \sim \{-1, 1\}^n$. Then,

$$d_{\mathcal{K}}(p(\mathbf{x}), \mathcal{N}(\mu, 1)) = O(\sqrt{\epsilon}).$$

If p(x) is not correlated with product of two linear forms, then it is distributed as a Gaussian.

Central limit theorem for higher degree polynomials

• Suppose the process goes on for j iterations. Either $j \le \epsilon^{-1} \log(1/\epsilon)$ or $j > \epsilon^{-1} \log(1/\epsilon)$.

• If $j \le \epsilon^{-1} \log(1/\epsilon)$, then this reduces the problem to $\exp(1/\epsilon)$ subproblems – each of which can be solved using Berry-Esséen.

▲□▶ ▲□▶ ▲ □▶ ▲ □▶ □ のへぐ

- If j ≤ ε⁻¹ log(1/ε), then this reduces the problem to exp(1/ε) subproblems each of which can be solved using Berry-Esséen.
- If $j > \epsilon^{-1} \log(1/\epsilon)$, we simply stop at $j = \epsilon^{-1} \log(1/\epsilon)$.
- The top $\epsilon^{-1}\log(1/\epsilon)$ weights capture most of the ℓ_2 mass.

- If $j > \epsilon^{-1} \log(1/\epsilon)$, we simply stop at $j = \epsilon^{-1} \log(1/\epsilon)$.
- The top $\epsilon^{-1}\log(1/\epsilon)$ weights capture most of the ℓ_2 mass.
- Non-trivial: Since ε⁻¹ log(1/ε) weights capture most of the mass of the vector w, we can just consider the halfspace over these variables.

- Meta idea: If the condition of CLT is met, apply.
- If it is not met, then restrict a variable and recurse.
- Meta-idea repeated in several works in derandomization which use limit theorems.

• So far, we have seen central limit theorems which provide convergence in Kolmogorov distance.

▲□▶ ▲□▶ ▲ 三▶ ▲ 三▶ 三三 - のへぐ

- So far, we have seen central limit theorems which provide convergence in Kolmogorov distance.
- In other words, we choose a threshold x and compare $Pr[\mathbf{S} \le x]$ with $Pr[\mathbf{Z} \le x]$.

- So far, we have seen central limit theorems which provide convergence in Kolmogorov distance.
- In other words, we choose a threshold x and compare $Pr[\mathbf{S} \le x]$ with $Pr[\mathbf{Z} \le x]$.
- It is possible to sometimes get convergence in stronger metrics.

Theorem (Chen-Goldstein-Shao)

Let $X_1, X_2, ..., X_n$ be independent Bernoulli random variables such that $\mathbf{S} = \sum X_i$ has mean μ and variance σ^2 . Then,

$$\|\mathbf{S} - \mathcal{N}_{\mathsf{disc}}(\mu, \sigma^2)\|_1 = O(\sigma^{-1}).$$

Theorem (Chen-Goldstein-Shao)

Let $X_1, X_2, ..., X_n$ be independent Bernoulli random variables such that $\mathbf{S} = \sum X_i$ has mean μ and variance σ^2 . Then,

$$\|\mathbf{S} - \mathcal{N}_{\mathsf{disc}}(\mu, \sigma^2)\|_1 = O(\sigma^{-1}).$$

Discrete CLTs have found many applications in derandomization and learning.

Let $X_1, X_2, ..., X_n$ be independent Bernoulli random variables such that $\mathbf{S} = \sum X_i$ has mean μ and variance σ^2 . Then,

$$\|\mathbf{S} - \mathcal{N}_{\mathsf{disc}}(\mu, \sigma^2)\|_1 = O(\sigma^{-1}).$$

Discrete CLTs have found many applications in derandomization and learning.

Also check out the new discrete CLTs proven by Valiant-Valiant, Daskalakis-Kamath-Tzamos and many others.

• Recall: Sum of *n*-i.i.d. random variables converges to a Gaussian at a rate of $O(n^{-1/2})$.

▲□▶ ▲□▶ ▲ 三▶ ▲ 三▶ 三三 - のへぐ

- Recall: Sum of n-i.i.d. random variables converges to a Gaussian at a rate of O(n^{-1/2}).
- Without more conditions, not possible to beat $O(n^{-1/2})$.
- However, if the limiting distribution can include non-Gaussian distributions, we can get better than $n^{-1/2}$ convergence rate.
