Vlad Shchogolev vs299@columbia.edu Entity Resolution

# Outline

#### Introduction

- What is Entity Resolution?
- Motivation
- 2 Background
  - Formal Definition
  - Efficieny Considerations
  - Measuring Text Similarity
  - Other approaches

#### 3 Methodology

- Clustering author references
- Learning distance function
- Clustering experiment

< ロ > < 同 > < 三 > .

What is Entity Resolution? Motivation

イロト イポト イヨト イヨト

3

- Given: a table of records, each record has a number of "fields".
- Problem: decide which pairs of records refer to the same "entity".
- Variation: given two tables, pair up matching records

What is Entity Resolution? Motivation

(日)

#### A new name for an old research area

- Record linkage
  - Originally studied by Dunn, 1946
  - Formalized by Fellegi and Sunter, 1969
- Merge/purge problem
- Data matching, object identity problem
- Coreference resolution, reference reconciliation, etc.

What is Entity Resolution? Motivation

イロト イポト イヨト イヨト

3

#### Why is this useful?

- Historical research
- Medical research
- Government record-keeping
- Tracking terrorists
- Wal-Mart
- Yahoo Local, Google Local
- Bibliographic citations

Formal Definition Efficiency Considerations Measuring Text Similarity Other approaches

イロト イポト イヨト イヨト

## **Formal Definition**

- Two datasets A and B, and let  $(a, b) \in A \times B$ .
- Also define *M* as the set of matched pairs (*a* = *b*) and *U* as the set of unmatched pairs.
- For a given pair, there is a list of comparison values for  $(c_1, \ldots c_n)$  where  $c_k$  is the comparison value for the  $k^{\text{th}}$  field of the item.

Formal Definition Efficiency Considerations Measuring Text Similarity Other approaches

ヘロト ヘ戸ト ヘヨト ヘヨト

Probabilistic Model, Fellegi and Sunter

- Define quantities  $m_k = P\{c_k = 0 | (a, b) \in M\}$  and  $u_k = P\{c_k = 0 | (a, b) \in U\}$
- Assume independence assumption (!)
- Weight assigned to each component is:

$$w_k = egin{cases} \log(m_k/u_k) & ext{if } c_k = 0, \ \log(1-m_k)/(1-u_k)) & ext{if } c_k = 1. \end{cases}$$

Equivalent to Naive Bayes

Formal Definition Efficiency Considerations Measuring Text Similarity Other approaches

(日)

- Need methods to find candidate pairs
- McCallum, Nigam, Ungar introduced "canopies" approach: clustering is performed in two stages, starting with a rough stage that divides data into overlapping subsets
- If clustering measures distance to cluster using cluster centroid, and canopy is larger than true cluster, nothing is lost.

Formal Definition Efficiency Considerations Measuring Text Similarity Other approaches

ヘロト ヘアト ヘヨト

# Clustering bibliographic references

- Goal was to compute the citation graph for research papers
- First pass: used a fast TF-IDF approach
- Second pass: used an expensive string edit distance computation, combined with a HMM for field extraction
- Results in equally good accuracy, but orders of magnitude faster

Formal Definition Efficiency Considerations Measuring Text Similarity Other approaches

- ⊒ →

# Measuring Text Similarity

Several methods exist to construct a similarity measure for text:

- edit distance (customizable costs)
- Jaro's algorithm (transpositions)
- character N-grams
- TF-IDF
- string kernels
- term-vector dot product
- soundex

Research typically finds that no single method is best

æ

# Refinements

Minton, Nanjo et al. introduced "transformation graphs" to handle higher level concepts:

- synonyms
- misspelling
- abbreviation
- acronym
- concatenation

Again, a Naive Bayes approach is used to learn weights for transformations.

Formal Definition Efficiency Considerations Measuring Text Similarity Other approaches

イロト イポト イヨト イヨト

#### Domain-independent approach

- Monge and Elkan suggest a "domain-independent" approach
- Each record is treat as a single long string
- Similarity is measured using edit distance

Clustering authors Learning distance function Clustering experiment

・ロト ・ ア・ ・ ヨト ・ ヨト

# Clustering author references

- A related problem to bibliographic references
- Experiment run on a large biology research corpus
- Goal is to determine when two matching names (e.g. Smith J.) refer to the same person
- Extra structure: social network consisting of co-authorship edges

Clustering authors Learning distance function Clustering experiment

イロト イポト イヨト イヨト

# Learning distance function

- Similar to distance metric learning paper, but not in Euclidean space
- Not domain-independent
- Domain knowledge used to pick from one of 3 comparison functions for each field:
  - equality
  - set intersection
  - character N-gram similarity
- Most important feature: number of common co-authors

Clustering authors Learning distance function Clustering experiment

・ロ・ ・ 四・ ・ ヨ・ ・ ヨ・

# Clustering experiment

- Clustering name references can be useful for judging co-authorship importance
- Tried experiments with simple Greedy Agglomerative Clustering.
- Measured within-cluster dispersion at each clustering step:
  - Data is clustered into k clusters  $C_1, \ldots C_k$
  - Sum of pairwise distances:  $D_r = \sum_{i,j \in C_r} d_{i,j}$
  - Dispersion measure:  $W_k = \sum_{r=1}^k \frac{1}{2n_r} D_r$

#### **Gap Statistic**

- Can we estimate the true number of clusters?
- Define Gap Statistic (Tibshirani et al. 2000)

$$Gap_n(k) = E_n^*(\log(W_k)) - \log(W_k)$$

- Expectation is over a sample from reference distribution
- The quantity  $log(W_k)$  can be thought of as log-likelihood

Clustering authors Learning distance function Clustering experiment

ヘロト 人間 とくほとく ほとう

э.

# **Reference distribution**

- $Gap_n(k) = E_n^*(\log(W_k)) \log(W_k)$
- For uniform distribution, expectation should decrease at the rate (2/p) log k.
- Better: a uniform distribution over a box align with the principal components.
- Goal is to produce evidence against the null model (single cluster)

Clustering authors Learning distance function Clustering experiment

くロト (過) (目) (日)

æ

#### **Estimation Procedure**

- Sample *B* Monte Carlo reference datasets from reference distribution
- Cluster each sampled dataset
- Estimate the gap:

$$Gap(k) = (1/B) \sum_{b} \log(W_{kb}^*) - \log(W_k)$$

• Pick smallest k such that  $Gap(k) > Gap(k+1) - s_{k+1}$ 

Clustering authors Learning distance function Clustering experiment

くロト (過) (目) (日)

ъ

#### **Estimation Procedure**

- Estimation performs poorly; reference distribution not appropriate?
- Euclidean distance metric not appropriate for high dimensions
- However: have evidence that  $W_k$  graph has some signal

Clustering authors Learning distance function Clustering experiment

ヘロト ヘワト ヘビト ヘビト

ъ

#### Two within-cluster dispersion graphs

Vlad Shchogolev vs299@columbia.edu Entity Resolution

- Rethink cluster estimation for this class of problems
- Distance metric learning works well, but...
- Should take advantage of additional structure
