Research Interests

Operating systems, software error detection, security, and storage systems.

Education

Ph.D. in Computer Science, 2008 STANFORD UNIVERSITY
Dissertation: Automatically Finding Serious Storage System Errors
Advisor: Dawson Engler

M.S. in Computer Science, 2002 STANFORD UNIVERSITY

B.S. in Computer Science, 2000 TSINGHUA UNIVERSITY, CHINA
Entrance exam waived based on outstanding high-school record

Special academic program, 1995-1997 TSINGHUA UNIVERSITY, CHINA
Only 60 out of about 2000 freshmen selected

Honors and Awards

2004 Best Paper Award of the Sixth USENIX Symposium on Operating Systems Design and Implementation (OSDI)

2003 Stanford School of Engineering Fellowship

2002 Siebel Scholarship

1995-1997 Tsinghua Outstanding Scholarship for Undergraduates

Working Experience

2007-2008 **Researcher** Microsoft Research, Silicon Valley

Building tools to check distributed systems. Led the design, implementation, and evaluation of MODIST, a lightweight, general system that systematically, comprehensively checks distributed system against many possible failures for errors. Distributed systems are notoriously hard to get right due to complicated interactions between different components and unpredictable failures, events, and message deliveries. MODIST is a lightweight checker for general distributed systems using implementation-level model checking techniques. It imposes no programming model, has no language restriction, requires little effort to use, and yet can be extended with programmer specified domain knowledge to improve coverage and performance. MODIST achieves its generality by interposition on the API between the application and the underlying OS for faithful and deterministic failure simulation. It is made practical through effective state reduction techniques, including using novel state signatures for duplicate state detection, and separating system-level control and application-level state exploration. MODIST has been applied to two distributed systems for large-scale clusters, both implementing proven-correct protocols. One of them has been deployed for more than 2 years to manage clusters with up to thousands of machines. A total of 28 bugs were discovered and 6

of them surface only in rare cases involving message ordering and crashes; those cases are difficult to detect without model checking.

Research Assistant

Stanford University

2004–2006

Automatically finding serious storage system errors using model checking. Developed a new approach to check storage systems. Led the design, implementation, and evaluation of two checking frameworks, FiSC [2] [6] and EXPLODE [3] [5], which formed my thesis work. Adapted ideas from model checking, a formal verification technique, to find unrecoverable data-loss errors (e.g. file system root corruptions).

I designed and built FiSC to thoroughly check file systems. Despite the wildly-different, poorly-specified guarantees provided by these file systems, I invented a set of powerful checks that require little FS-specific knowledge to apply. For example, one of them checked the atomicity guarantees provided by write-ahead-logging and found eight data-loss errors. FiSC found over 33 errors in four widely-used, well-tested Linux file systems, 11 of which can cause data loss, 21 of which were serious enough to lead to immediate kernel patches within two days. The paper from this work won Best Paper Award of the Sixth USENIX Symposium on Operating Systems Design and Implementation (OSDI'04).

I designed and built EXPLODE to generalize the above approach to other storage systems, and to make checking lightweight. Instead of porting a system to run inside a model checker, I invented an *in-situ* checking architecture that interlaces the mechanisms needed for comprehensive checking with the checked system. This architecture drastically reduced the checking overhead by several orders of magnitude. It also reduced the invasive infrastructure needed (down to a single device driver in EXPLODE). I created a C++ checking interface in which developers simply write a few hundred lines of code to check their storage system. Along with my colleagues, I checked a wide range of seventeen storage systems, including three version control software, a database, NFS, ten file systems, a software RAID and a popular commercial virtual machine. We found errors in every system checked, 36 errors in total, most of which can cause serious data loss.

2005–2006

Automatically generating malicious disks using symbolic execution. With Can Sar, Paul Twohey, Cristian Cadar and my advisor Dawson Engler, co-proposed a threat model in which malicious disks crash or exploit an OS kernel through the file system mount interface. We used EXE, a testcase generator using symbolic executions, to discover nine malicious disk images [4]. I identified several drawbacks of EXE, and proposed two optimizations to make the work possible. This application greatly improved EXE and remains as its most significant benchmark.

2003

Extensible, expressive and lightweight annotation language and system. Led the design, implementation, and evaluation of MECA, an extensible, expressive system and language for statically finding security errors [8]. Extended C grammar and modified the GNU C Compiler to allow programmers to declare and use domain-specific annotations as inlined comments in their code. Invented several practical constructs to effectively annotate large bodies of code and suppress false positives. To reduce annotation overhead, I used aggressive compiler analysis and statistical analysis to infer missing annotations. The most thorough case study of MECA, a checker that detects invalid use of user-provided pointers in OS kernel, used only 75 manual annotations to automatically derive more than ten thousand missing ones and check millions of lines of code in the Linux kernel. It found 44 security holes with only 8 false positives.

2004

Correlation Exploitation in Error Ranking. With Ted Kremenek, Ken Ashcraft, and Dawson Engler, co-proposed an online ranking algorithm for error report inspection [7]. It uses feedbacks from users to dynamically rank likely errors over false positives, by exploring correlations in error reports.

2001

An empirical study of OS errors. With Andy Chou, Dawson Engler and others, collaboratively studied error patterns in kernel code using roughly 1000 unique, automatically-

detected errors on 11 Linux kernel releases over 7 years [9]. One interesting pattern was that Linux device drivers are up to ten times buggier than other kernel code.

Summer 2005

Summer Intern

Microsoft Research, Silicon Valley

Mentor: Lidong Zhou, John MacCormick

Load balancing in distributed systems. Surveyed theory results on load balancing (the classic balls-into-bins problem). Based on the study, I co-designed and evaluated a distributed load balancing scheme that used multiple hash functions to achieve both good balance and high availability, in the presence of incremental system expansions, server failures, and load changes. This scheme has been extended and deployed in a distributed data store at Microsoft Research. The results from this work will appear in [1].

Teaching and Supervisory Experience

2003–now

With my advisor, I co-supervised three research projects: EXPLODE, FiSC, and MECA.

2006

Teaching Assistant, Stanford course CS240, Advanced Topics in Operating Systems

2005–2006

Informally advised a Bachelor Honors Thesis

2005

Teaching Assistant, Stanford course CS240, Advanced Topics in Operating Systems
