Sequence-to-sequence models

- · Introduced in Sutskever et al. (2014) and Cho et al. (2014)
- Combine a sequence encoder for the source language with a sequence decoder for the target language
 - 1. Encode source language tokens until <EOS> obtained
 - 2. Use final encoder hidden state as context vector
 - 3. Decode target language tokens until <EOS> obtained
- \cdot Use gated units (LSTMs or GRUs) to overcome vanishing gradients
- Beam search decoding through softmax scores

Sequence-to-sequence learning

12

▲□▶ ▲□▶ ▲三▶ ▲三▶ 三三 - のへ⊙

- Backpropagation through repeated non-linear transformations (sigmoid, tanh) leads to vanishing gradients
 - RNNs cannot easily model long-range dependencies
 - Performance degrades with longer sequences
- LSTM (Hochreiter & Schmidhuber, 1997) adds a memory cell which is only affected by linear interactions
- \cdot Gates with sigmoid activations are used to modulate:
 - additions from the current input (input gate)
 - contributions to the next hidden state (output gate)
 - the amount of memory decayed (forget gate) (Gers et al., 1999)

$$h_t = \tanh(W_{\mathsf{x}\mathsf{h}}^\top x_t + W_{\mathsf{h}\mathsf{h}}^\top h_{t-1})$$

$$h_t = \mathbf{o_t} \odot \tanh(c_t)$$

▲ロト ▲母 ト ▲ 臣 ト ▲ 臣 ト ○ 臣 - のへぐ

- Inspired by LSTM but with no memory cell (Cho et al., 2014)
- · Gates with sigmoid activations are used to control:
 - contributions of the previous hidden state to a new state (reset gate)
 - the balance between previous and new states for the next hidden state (update gate)
- Requires fewer parameters but performs similarly to LSTM in practice (Chung et al., 2014)

$$\tilde{h}_t = \tanh(W_{\mathbf{xh}}^\top x_t + W_{\mathbf{hh}}^\top h_{t-1})$$
$$h_t = \tilde{h}_t$$

$$\mathbf{r_t} = \sigma(W_{\mathsf{rx}}^\top x_t + W_{\mathsf{rh}}^\top h_{t-1})$$

Sequence-to-sequence models

- + First end-to-end neural architecture for machine translation
- + No alignments required, just parallel data
- + Encoders produce meaningful sentence embeddings
- Does not outperform phrase-based MT techniques
- Performance degrades for longer sentences
- Need to reverse the input for better performance

Method	test BLEU score (ntst14)
Baseline System [29]	33.30
Single forward LSTM, beam size 12	26.17
Single reversed LSTM, beam size 12	30.59

Attention mechanism

• Fixed context vector is a bottleneck for performance in encoder-decoder architectures

- Bahdanau et al. (2015) introduce a dynamic context vector that changes with each decoder timestep
 - Weighted average over all encoder hidden states
 - Weights ("attention") conditioned on current decoder hidden state
- Allows gradients to flow directly from decoding errors to relevant encoder hidden states, thus robust to vanishing gradients

Moses	33.30	35.63

– Runtime for inference is $\mathcal{O}(mn)$ instead of $\mathcal{O}(m+n)$ without attention

Outline

- Encoder-decoder architectures
 - RNN encoders & decoders
 - Sequence-to-sequence models
 - LSTMs & GRUs
- Attention mechanism
 - Dynamic contexts
 - Induced alignments
- $\circ\,$ Scaling up
 - $\cdot\,$ Google NMT
 - \cdot Sub-word units
 - · Sequence-level training
 - Multilingual translation
- Transformers
 - \cdot Self-attention
 - Induced structure

Scaling up

- · Practical translation systems typically rely on phrase-based MT
 - NMT does scale easily to large vocabularies and rare words
 - Slower inference for large neural networks
 - NMT sometimes fails to fully translate all of the input
- Wu et al. (2016) describes a production-grade NMT system evaluated against phrase-based MT for Google Translate

	PBMT	GNMT	Human	Relative
				Improvement
$\operatorname{English} \to \operatorname{Spanish}$	4.885	5.428	5.504	87%
$\mathrm{English} \to \mathrm{French}$	4.932	5.295	5.496	64%
$\mathrm{English} \to \mathrm{Chinese}$	4.035	4.594	4.987	58%
$\text{Spanish} \to \text{English}$	4.872	5.187	5.372	63%
$\mathrm{French} \to \mathrm{English}$	5.046	5.343	5.404	83%
$Chinese \rightarrow English$	3.694	4.263	4.636	60%

Scaling up: GNMT

- Sequence-to-sequence model with attention (Wu et al., 2016)
 Encoder: 8 LSTM layers; bottom layer bidirectional
 Decoder: 8 LSTM layers; bottom layer provides attention context
- · All layers loaded on separate GPUs

Scaling up: Residual connections

Stacked LSTMs with residual connections (He et al., 2015)

- Layer inputs added element-wise to outputs
- Activations model differences between layer inputs and targets
- More robust to vanishing gradients in deep architectures

Scaling up: Sub-word units

· Infrequent words replaced with sub-words to reduce vocabulary

Jet makers feud over seat width with big orders at stake ↓ _J et _makers _fe ud _over _seat _width _with _big _orders _at _stake

- · Various corpus-based techniques to identify sub-words including
 - WordPieceModel (Schuster & Nakajima, 2012)
 - Byte Pair Encoding (Sennrich et al., 2016)
- · Available implementations:
 - sentencepiece
 - subword-nmt

Scaling up: Sequence-level training

- NMT models are trained on the word level with cross-entropy loss but evaluated with *sequence-level* metrics like BLEU, which are non-differentiable
- Model parameters θ can also be refined against any non-differentiable measure R(x, y) using reinforcement learning

$$\nabla_{\theta} \mathbb{E}_{\mathcal{D}} \left[R(x, y) \right] = \sum_{\langle x, y \rangle \in \mathcal{D}} R(x, y) \cdot \nabla_{\theta} p(y|x; \theta)$$
$$= \sum_{\langle x, y \rangle \in \mathcal{D}} R(x, y) \cdot \nabla_{\theta} p(y|x; \theta) \cdot \frac{p(y|x; \theta)}{p(y|x; \theta)}$$
$$= \sum_{\langle x, y \rangle \in \mathcal{D}} R(x, y) \cdot \nabla_{\theta} \log p(y|x; \theta) \cdot p(y|x; \theta)$$
$$= \mathbb{E}_{\mathcal{D}} \left[R(x, y) \cdot \nabla_{\theta} \log p(y|x; \theta) \right]$$

Scaling up: Multilingual MT

- Johnson et al. (2016) proposes a simple change to translate between *multiple* languages with a single NMT model
 - A token is added to the input sequence to indicate the target language for translation
 - Vocabulary and parameters are shared across languages
- + Can improve translation for low-resource languages with little parallel data
- + Enables zero-shot translation for language pairs with no parallel data

Scaling up: Multilingual MT

t-SNE projections of learned representations of 74 sentences and different translations in English, Japanese and Korean

Johnson et al. (2016)

Scaled dot-product attention

 The original additive attention (Bahdanau et al., 2015) is a single-layer feed-forward network over a concatenated query and key.

$$\mathsf{score}(q,k) = u_{\mathsf{qk}}^{\top} \mathsf{tanh}(W_{\mathsf{qk}}^{\top}[q;k])$$

• Scaled dot-product attention (Vaswani et al., 2017) instead uses a simple dot product between the projected query and key (after a linear projection), normalized by the key dimensionality d_k

$$\operatorname{score}(q,k) = \frac{q^{\top}k}{\sqrt{d_k}}$$

where $q = W_{\mathbf{q}}^{\top}q'$ and $k = W_{\mathbf{k}}^{\top}k'$ Note: values are projected separately $v = W_{\mathbf{v}}^{\top}v'$

• The sequential computation of RNNs prevents parallelization for inference and also de-emphasizes long-range dependencies

- Vaswani et al., (2017) introduces a sequence model with recurrent connections replaced by *self-attention*
 - Hidden states for each input token are produced by attending to the input sequence using the token as a query
 - Information about word positions must by injected via *position embeddings* in the input
- \cdot Recurrent layers are replaced by self-attention layers which can be stacked, each with
 - Scaled dot-product attention
 - o Multiple attention heads, projected down to the input dimensionality
 - Unseen tokens masked out (in the decoder)

Self-attention: Anaphora resolution

- + No recurrence, so inference can be parallelized
- + Improved runtime and performance on translation + other tasks
- + Scaled dot-product attention is efficient
- + Self-attention layers appear to capture some linguistic structure
- $\mathcal{O}(n^2)$ comparisons for each layer (unless restricted)
- Positional embeddings are necessary to account for ordering of input
