

## CPL: A Language for User Control of Internet Telephony Services

### Status of this Memo

This document is an Internet-Draft and is in full conformance with all provisions of Section 10 of RFC2026.

Internet-Drafts are working documents of the Internet Engineering Task Force (IETF), its areas, and its working groups. Note that other groups may also distribute working documents as Internet-Drafts.

Internet-Drafts are draft documents valid for a maximum of six months and may be updated, replaced, or obsoleted by other documents at any time. It is inappropriate to use Internet-Drafts as reference material or to cite them other than as “work in progress.”

The list of current Internet-Drafts can be accessed at <http://www.ietf.org/ietf/1id-abstracts.txt>

To view the list Internet-Draft Shadow Directories, see <http://www.ietf.org/shadow.html>.

### Abstract

The Call Processing Language (CPL) is a language that can be used to describe and control Internet telephony services. It is designed to be implementable on either network servers or user agent servers. It is meant to be simple, extensible, easily edited by graphical clients, and independent of operating system or signalling protocol. It is suitable for running on a server where users may not be allowed to execute arbitrary programs, as it has no variables, loops, or ability to run external programs.

This document is a product of the IP Telephony (IPTEL) working group of the Internet Engineering Task Force. Comments are solicited and should be addressed to the working group’s mailing list at [iptel@ietf.org](mailto:iptel@ietf.org) and/or the authors.

## 1 Introduction

The Call Processing Language (CPL) is a language that can be used to describe and control Internet telephony services. It is not tied to any particular signalling architecture or protocol; it is anticipated that it will be used with both the Session Initiation Protocol (SIP) [1] and H.323 [16].

CPL is powerful enough to describe a large number of services and features, but it is limited in power so that it can run safely in Internet telephony servers. The intention is to make it impossible for users to do anything more complex (and dangerous) than describing Internet telephony services. The language is not Turing-complete, and provides no way to write loops or recursion.

CPL is also designed to be easily created and edited by graphical tools. It is based on the Extensible Markup Language (XML) [2], so parsing it is easy and many parsers for it are publicly available. The structure of the language maps closely to its behavior, so an editor can understand any valid script, even ones written by hand. The language is also designed so that a server can easily confirm scripts' validity at the time they are delivered to it, rather than discovering them while a call is being processed.

Implementations of CPL are expected to take place both in Internet telephony servers and in advanced clients; both can usefully process and direct users' calls. This document primarily addresses the usage in servers. A mechanism will be needed to transport scripts between clients and servers; this document does not describe such a mechanism, but related documents will.

The framework and requirements for the CPL architecture are described in RFC 2824, "Call Processing Language Framework and Requirements" [17].

## 1.1 Conventions of This Document

In this document, the key words "MUST", "MUST NOT", "REQUIRED", "SHALL", "SHALL NOT", "SHOULD", "SHOULD NOT", "RECOMMENDED", "MAY", and "OPTIONAL" are to be interpreted as described in RFC 2119 [3] and indicate requirement levels for compliant CPL implementations.

Some paragraphs are indented, like this; they give motivations of design choices, advice to implementors, or thoughts on future development of or extensions to CPL. They are not essential to the specification of the language, and are non-normative.

## 2 Structure of CPL Scripts

### 2.1 High-level Structure

A CPL script consists of two types of information: *ancillary information* about the script, and *call processing actions*.

A call processing action is a structured tree that describes the operations and decisions a telephony signalling server performs on a call set-up event. There are two types of call processing actions: *top-level actions* and *subactions*. Top-level actions are actions that are triggered by signalling events that arrive at the server. Two top-level actions are defined: *incoming*, the action performed when a call arrives whose destination is the owner of the script; and *outgoing*, the action performed when a call arrives whose originator is the owner of the script. Subactions are actions which can be called from other actions. CPL forbids subactions from being called recursively: see Section 8.

Ancillary information is information which is necessary for a server to correctly process a script, but which does not directly describe any operations or decisions. Currently, no ancillary information is defined, but the section is reserved for use by extensions.

### 2.2 Abstract Structure of a Call Processing Action

Abstractly, a call processing action is described by a collection of nodes, which describe operations that can be performed or decisions that can be made. A node may have several parameters, which specify the precise behavior of the node; they usually also have outputs, which depend on the result of the decision or action.

For a graphical representation of a CPL action, see Figure 1. Nodes and outputs can be thought of informally as boxes and arrows; CPL is designed so that actions can be conveniently edited graphically using this representation. Nodes are arranged in a tree, starting at a single root node; outputs of nodes are

connected to additional nodes. When an action is run, the action or decision described by the action's top-level node is performed; based on the result of that node, the server follows one of the node's outputs, and the subsequent node it points to is performed; this process continues until a node with no specified outputs is reached. Because the graph is acyclic, this will occur after a bounded and predictable number of nodes are visited.

If an output to a node does not point to another node, it indicates that the CPL server should perform a node- or protocol-specific action. Some nodes have specific default behavior associated with them; for others, the default behavior is implicit in the underlying signalling protocol, or can be configured by the administrator of the server. For further details on this, see Section 10.

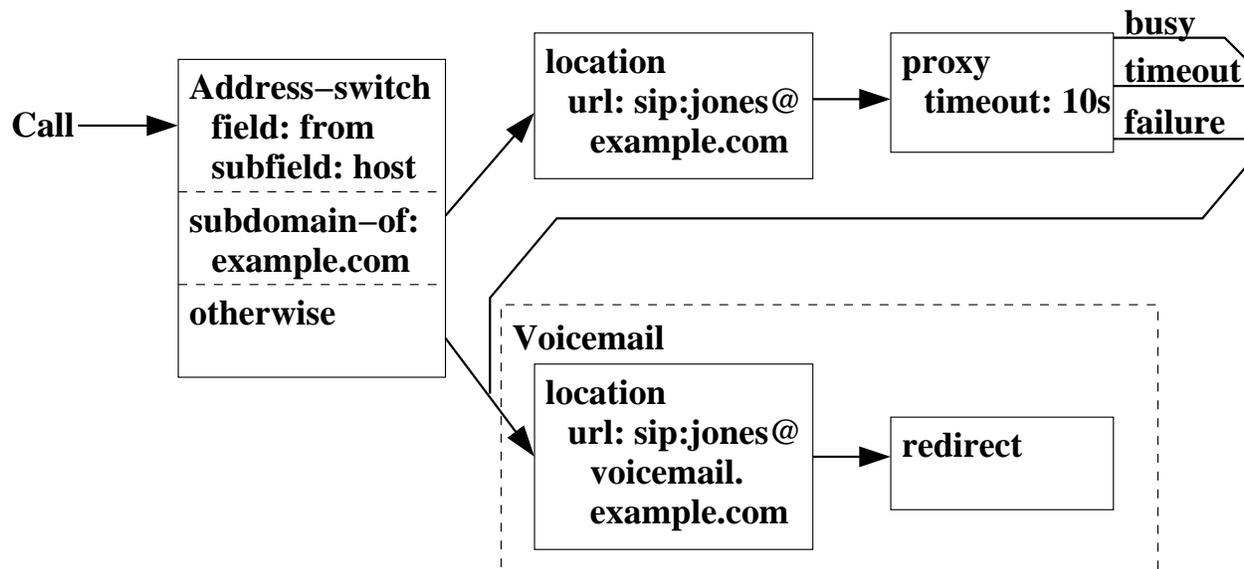

Figure 1: Sample CPL Action: Graphical Version

### 2.3 Location Model

For flexibility, one piece of information necessary for CPL is not given as node parameters: the set of locations to which a call is to be directed. Instead, this set of locations is stored as an implicit global variable throughout the execution of a processing action (and its subactions). This allows locations to be retrieved from external sources, filtered, and so forth, without requiring general language support for such operations (which could harm the simplicity and tractability of understanding the language). The specific operations which add, retrieve, or filter location sets are given in Section 5.

For the incoming top-level call processing action, the location set is initialized to the empty set. For the outgoing action, it is initialized to the destination address of the call.

### 2.4 XML Structure

Syntactically, CPL scripts are represented by XML documents. XML is thoroughly specified by the XML specification [2], and implementors of this specification should be familiar with that document, but as a brief overview, XML consists of a hierarchical structure of tags; each tag can have a number of attributes. It is

```
<?xml version="1.0" encoding="UTF-8"?>
<cpl xmlns="urn:ietf:params:xml:ns:cpl"
  xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
  xsi:schemaLocation="urn:ietf:params:xml:ns:cpl cpl.xsd ">
  <subaction id="voicemail">
    <location url="sip:jones@voicemail.example.com">
      <redirect />
    </location>
  </subaction>
  <incoming>
    <address-switch field="origin" subfield="host">
      <address subdomain-of="example.com">
        <location url="sip:jones@example.com">
          <proxy timeout="10">
            <busy> <sub ref="voicemail" /> </busy>
            <noanswer> <sub ref="voicemail" /> </noanswer>
            <failure> <sub ref="voicemail" /> </failure>
          </proxy>
        </location>
      </address>
      <otherwise>
        <sub ref="voicemail" />
      </otherwise>
    </address-switch>
  </incoming>
</cpl>
```

Figure 2: Sample CPL Script: XML Version

visually and structurally very similar to HTML [18], as both languages are simplifications of the earlier and larger standard SGML [19].

See Figure 2 for the XML document corresponding to the graphical representation of the CPL script in Figure 1. Both nodes and outputs in CPL are represented by XML tags; parameters are represented by XML tag attributes. Typically, node tags contain output tags, and vice-versa (with a few exceptions: see Sections 5.1, 5.3, 7.1, and 7.2).

The connection between the output of a node and another node is represented by enclosing the tag representing the pointed-to node inside the tag for the outer node's output. Convergence (several outputs pointing to a single node) is represented by subactions, discussed further in Section 8.

The higher-level structure of a CPL script is represented by tags corresponding to each piece of ancillary information, subactions, and top-level actions, in order. This higher-level information is all enclosed in a special tag `cpl`, the outermost tag of the XML document.

A complete XML Schema for CPL is provided in Appendix C. The remainder of the main sections of this document describe the semantics of CPL, while giving its syntax informally. For the formal syntax, please see the appendix.

### 3 Script Structure: Overview

As mentioned, a CPL script consists of ancillary information, subactions, and top-level actions. The full syntax of the `cpl` node is given in Figure 3.

Tag:	cpl		
Parameters:	None		
Sub-tags:	ancillary	See Section 9	
	subaction	See Section 8	
	outgoing	Top-level actions to take on this user's outgoing calls	
	incoming	Top-level actions to take on this user's incoming calls	

Figure 3: Syntax of the top-level `cpl` tag

Call processing actions, both top-level actions and sub-actions, consist of a tree of nodes and outputs. Nodes and outputs are both described by XML tags. There are four categories of CPL nodes: *switches*, which represent choices a CPL script can make; *location modifiers*, which add or remove locations from the location set; *signalling operations*, which cause signalling events in the underlying protocol; and *non-signalling operations*, which trigger behavior which does not effect the underlying protocol.

## 4 Switches

Switches represent choices a CPL script can make, based on either attributes of the original call request or items independent of the call.

All switches are arranged as a list of conditions that can match a variable. Each condition corresponds to a node output; the output points to the next node to execute if the condition was true. The conditions are tried in the order they are presented in the script; the output corresponding to the first node to match is taken.

There are two special switch outputs that apply to every switch type. The output `not-present`, which MAY occur anywhere in the list of outputs, is true if the variable the switch was to match was not present in the original call setup request. (In this document, this is sometimes described by saying that the information is "absent".) The output `otherwise`, which MUST be the last output specified if it is present, matches if no other condition matched.

If no condition matches and no `otherwise` output was present in the script, the default script behavior is taken. See Section 10 for more information on this.

Switches MAY contain no outputs. They MAY contain only an `otherwise` output.

Such switches are not particularly useful, but might be created by tools which automatically generate CPL scripts.

### 4.1 Address Switches

Address switches allow a CPL script to make decisions based on one of the addresses present in the original call request. They are summarized in Figure 4.

Node:	address-switch	
Outputs:	address	Specific addresses to match
Parameters:	field	origin, destination, or original-destination
	subfield	address-type, user, host, port, tel, or display (also: password and alias-type)
Output:	address	
Parameters:	is	Exact match
	contains	Substring match (for display only)
	subdomain-of	Sub-domain match (for host, tel)

Figure 4: Syntax of the address-switch node

Address switches have two node parameters: `field`, and `subfield`. The mandatory `field` parameter allows the script to specify which address is to be considered for the switch: either the call's origin address (field `origin`), its current destination address (field `destination`), or its original destination (field `original-destination`), the destination the call had before any earlier forwarding was invoked. Servers MAY define additional field values.

The optional `subfield` specifies what part of the address is to be considered. The possible subfield values are: `address-type`, `user`, `host`, `port`, `tel`, and `display`. Additional subfield values MAY be defined for protocol-specific values. (The subfield `password` is defined for SIP in Section 4.1.1; the subfield `alias-type` is defined for H.323 in Appendix B.1.) If no subfield is specified, the "entire" address is matched; the precise meaning of this is defined for each underlying signalling protocol. Servers MAY define additional subfield values.

The subfields are defined as follows:

**address-type** This indicates the type of the underlying address; i.e., the URI scheme, if the address can be represented by a URI. The types specifically discussed by this document are `sip`, `tel`, and `h323`. The address type is not case-sensitive. It has a value for all defined address types.

**user** This subfield of the address indicates, for e-mail style addresses, the user part of the address. For telephone number style address, it includes the subscriber number. This subfield is case-sensitive; it may be absent.

**host** This subfield of the address indicates the Internet host name or IP address corresponding to the address, in host name, IPv4, or IPv6 [4] textual representation format. Host names are compared as strings. IP addresses are compared numerically. (In particular, the presence or location of an IPv6 :: omitted-zero-bits block is not significant for matching purposes.) Host names are never equal to IP addresses — no DNS resolution is performed. IPv4 addresses are never equal to IPv6 addresses, even if the IPv6 address is a v4-in-v6 embedding. This subfield is not case sensitive, and may be absent.

For host names only, subdomain matching is supported with the `subdomain-of` match operator. The `subdomain-of` operator ignores leading dots in the hostname or match pattern, if any.

**port** This subfield indicates the TCP or UDP port number of the address, numerically in decimal format. It is not case sensitive, as it **MUST** only contain decimal digits. Leading zeros are ignored.

**tel** This subfield indicates a telephone subscriber number, if the address contains such a number. It is not case sensitive (the telephone numbers may contain the symbols ‘A’ ‘B’ ‘C’ and ‘D’), and may be absent. It may be matched using the **subdomain-of** match operator. Punctuation and separator characters in telephone numbers are discarded.

**display** This subfield indicates a “display name” or user-visible name corresponding to an address. It is a Unicode string, and is matched using the case-insensitive algorithm described in Section 4.2. The **contains** operator may be applied to it. It may be absent.

For any completely unknown subfield, the server **MAY** reject the script at the time it is submitted with an indication of the problem; if a script with an unknown subfield is executed, the server **MUST** consider the **not-present** output to be the valid one.

The **address** output tag may take exactly one of three possible parameters, indicating the kind of matching allowed.

**is** An output with this match operator is followed if the subfield being matched in the **address-switch** exactly matches the argument of the operator. It may be used for any subfield, or for the entire address if no subfield was specified.

**subdomain-of** This match operator applies only for the subfields **host** and **tel**. In the former case, it matches if the hostname being matched is a subdomain of the domain given in the argument of the match operator; thus, `subdomain-of="example.com"` would match the hostnames “example.com”, “research.example.com”, and “zaphod.sales.internal.example.com”. IP addresses may be given as arguments to this operator; however, they only match exactly. In the case of the **tel** subfield, the output matches if the telephone number being matched has a prefix that matches the argument of the match operator; `subdomain-of="1212555"` would match the telephone number “1 212 555 1212.”

**contains** This match operator applies only for the subfield **display**. The output matches if the display name being matched contains the argument of the match as a substring.

#### 4.1.1 Usage of **address-switch** with SIP

For SIP, the **origin** address corresponds to the address in the **From** header; **destination** corresponds to the **Request-URI**; and **original-destination** corresponds to the **To** header.

The **display** subfield of an address is the **display-name** part of the address, if it is present. Because of SIP’s syntax, the **destination** address field will never have a **display** subfield.

The **address-type** subfield of an address is the URI scheme of that address. Other address fields depend on that **address-type**.

For SIP URIs, the **user**, **host**, and **port** subfields correspond to the “user,” “host,” and “port” elements of the URI syntax. (Note that, following the definitions of RFC 3261 [1], a SIP URI which does not specify a port is not the same as an explicit port 5060; the former is indicated by an absent port subfield.) The **tel** subfield is defined to be the “user” part of the URI, with visual separators stripped, if the “**user=phone**” parameter is given to the URI, or if the server is otherwise configured to recognize the user part as a telephone

number. An additional subfield, **password** is defined to correspond to the “password” element of the SIP URI, and is case-sensitive. However, use of this field is NOT RECOMMENDED for general security reasons.

For tel URLs, the **tel** and **user** subfields are the subscriber name; in the former case, visual separators are stripped. The **host** and **port** subfields are both not present.

For h323 URLs, subfields MAY be set according to the scheme described in Appendix B.

For other URI schemes, only the **address-type** subfield is defined by this specification; servers MAY set other pre-defined subfields, or MAY support additional subfields.

If no subfield is specified for addresses in SIP messages, the string matched is the URI part of the address. For **is** matches, standard SIP URI matching rules are used; for **contains** matches, the URI is used verbatim.

## 4.2 String Switches

String switches allow a CPL script to make decisions based on free-form strings present in a call request. They are summarized in Figure 5.

Node:	string-switch	
Outputs:	string	Specific string to match
Parameters:	field	subject, organization, user-agent, or display
Output:	string	
Parameters:	is	Exact match
	contains	Substring match

Figure 5: Syntax of the **string-switch** node

String switches have one node parameter: **field**. The mandatory **field** parameter specifies which string is to be matched.

String switches are dependent on the call signalling protocol being used.

Five fields are defined, listed below. The value of each of these fields, except as specified, is a free-form Unicode string with no other structure defined.

**subject** The subject of the call.

**organization** The organization of the originator of the call.

**user-agent** The name of the program or device with which the call request was made.

**display** Free-form text associated with the call, intended to be displayed to the recipient, with no other semantics defined by the signalling protocol.

Strings are matched as case-insensitive Unicode strings, in the following manner. First, strings are canonicalized to the “Compatibility Composition” (KC) form, as specified in Unicode Technical Report 15 [5]. Then, strings are compared using locale-insensitive caseless mapping, as specified in Unicode Technical Report 21 [6].

Code to perform the first step, in Java and Perl, is available; see the links from Annex E of UTR 15 [5]. The case-insensitive string comparison in the Java standard class libraries already performs the second step; other Unicode-aware libraries should be similar.

The output tag of string matching is named **string**, and has a mandatory argument, one of **is** or **contains**, indicating whole-string match or substring match, respectively.

#### 4.2.1 Usage of **string-switch** with SIP

For SIP, the fields **subject**, **organization**, and **user-agent** correspond to the SIP header fields with the same name. These are used verbatim as they appear in the message.

The field **display** is not used, and is never present.

### 4.3 Language Switches

Language switches allow a CPL script to make decisions based on the languages in which the originator of the call wishes to communicate. They are summarized in Figure 6.

Node:	language-switch	
Outputs:	language	Specific string to match
Parameters:	None	
Output:	language	
Parameters:	matches	Match if the given language matches a language-range of the call.

Figure 6: Syntax of the **language-switch** node

Language switches take no parameters.

The **language** output takes one parameter, **matches**. The value of the parameter is a language-tag, as defined in RFC 3066 [7]. The caller may have specified a set of language-ranges, also as defined in RFC 3066. The CPL server checks each language-tag specified by the script against the language-ranges specified in the request.

See RFC 3066 for the details of how language-ranges match language-tags. Briefly, a language-range matches a language-tag if it exactly equals the tag, or if it exactly equals a prefix of the tag such that the first character following the prefix is "-".

If the caller specified the special language-range "\*", it is ignored for the purpose of matching. Languages with a q value of 0 are also ignored.

This switch **MAY** be not-present.

#### 4.3.1 Usage of **language-switch** with SIP

The language-ranges for the **language-switch** switch are obtained from the SIP **Accept-Language** header field. The switch is not-present if the initial SIP request did not contain this header field.

Note that because of CPL's first-match semantics in switches, q values other than 0 of the **Accept-Language** header fields are ignored.

#### 4.4 Time Switches

Time switches allow a CPL script to make decisions based on the time and/or date the script is being executed. They are summarized in Figure 7.

Time switches are independent of the underlying signalling protocol.

Node:	time-switch	
Outputs:	time	Specific time to match
Parameters:	tzid	RFC 2445 Time Zone Identifier
	tzurl	RFC 2445 Time Zone URL
Output:	time	
Parameters:	dtstart	Start of interval (RFC 2445 DATE-TIME)
	dtend	End of interval (RFC 2445 DATE-TIME)
	duration	Length of interval (RFC 2445 DURATION)
	freq	Frequency of recurrence (“secondly”, “minutely”, “hourly”, “daily”, “weekly”, “monthly”, or “yearly”)
	interval	How often the recurrence repeats
	until	Bound of recurrence (RFC 2445 DATE-TIME)
	count	Number of occurrences of recurrence
	bysecond	List of seconds within a minute
	byminute	List of minutes within an hour
	byhour	List of hours of the day
	byday	List of days of the week
	bymonthday	List of days of the month
	byyearday	List of days of the year
	byweekno	List of weeks of the year
	bymonth	List of months of the year
	wkst	First day of the work week
bysetpos	List of values within set of events specified	

Figure 7: Syntax of the time-switch node

Time switches are based closely on the specification of recurring intervals of time in the Internet Calendaring and Scheduling Core Object Specification (iCalendar COS), RFC 2445 [8].

This allows CPL scripts to be generated automatically from calendar books. It also allows us to re-use the extensive existing work specifying time intervals.

If future standards-track documents are published that update or obsolete RFC 2445, any changes or clarifications those documents make to recurrence handling apply to CPL time-switches as well.

An algorithm to determine whether an instant falls within a given recurrence is given in Appendix A.

The `time-switch` tag takes two optional parameters, `tzid` and `tzurl`, both of which are defined in RFC 2445 (Sections 4.8.3.1 and 4.8.3.5 respectively). The `tzid` is the identifying label by which a time zone definition is referenced. If it begins with a forward slash (solidus), it references a to-be-defined global time

zone registry; otherwise it is locally-defined at the server. The `tzurl` gives a network location from which an up-to-date `VTIMEZONE` definition for the timezone can be retrieved.

While `tzid` labels that do not begin with a forward slash are locally defined, it is RECOMMENDED that servers support at least the naming scheme used by Olson Time Zone database [9]. Examples of timezone databases that use the Olson scheme are the `zoneinfo` files on most Unix-like systems, and the standard Java `TimeZone` class.

Servers SHOULD resolve `tzid` and `tzurl` references to time zone definitions at the time the script is uploaded. They MAY periodically refresh these resolutions to obtain the most up-to-date definition of a time zone. If a `tzurl` becomes invalid, servers SHOULD remember the most recent valid data retrieved from the URL.

If a script is uploaded with a `tzid` and `tzurl` which the CPL server does not recognize or cannot resolve, it SHOULD diagnose and reject this at script upload time. If neither `tzid` nor `tzurl` are present, all non-UTC times within this time switch should be interpreted as being “floating” times, i.e. that they are specified in the local timezone of the CPL server.

Because of daylight-savings-time changes over the course of a year, it is necessary to specify time switches in a given timezone. UTC offsets are not sufficient, or a time-of-day routing rule which held between 9 am and 5 pm in the eastern United States would start holding between 8 am and 4 pm at the end of October.

Authors of CPL servers should be careful to handle correctly the intervals when local time is discontinuous, at the beginning or end of daylight-savings time. Note especially that some times may occur more than once when clocks are set back. The algorithm in Appendix A is believed to handle this correctly.

Time nodes specify a list of periods during which their output should be taken. They have two required parameters: `dtstart`, which specifies the beginning of the first period of the list, and exactly one of `dtend` or `duration`, which specify the ending time or the duration of the period, respectively. The `dtstart` and `dtend` parameters are formatted as iCalendar COS DATE-TIME values, as specified in Section 4.3.5 of RFC 2445 [8]. Because time zones are specified in the top-level time-switch tag, only forms 1 or 2 (floating or UTC times) can be used. The `duration` parameter is given as an iCalendar COS DURATION parameter, as specified in section 4.3.6 of RFC 2445. Both the DATE-TIME and the DURATION syntaxes are subsets of the corresponding syntaxes from ISO 8601 [20].

For a recurring interval, the `duration` parameter MUST be small enough such that subsequent intervals do not overlap. For non-recurring intervals, durations of any positive length are permitted. Zero-length and negative-length durations are not allowed.

If no other parameters are specified, a time node indicates only a single period of time. More complicated sets periods intervals are constructed as recurrences. A recurrence is specified by including the `freq` parameter, which indicates the type of recurrence rule. Parameters other than `dtstart`, `dtend`, and `duration` SHOULD NOT be specified unless `freq` is present, though CPL servers SHOULD accept scripts with such parameters present, and ignore the other parameters.

The `freq` parameter takes one of the following values: `secondly`, to specify repeating periods based on an interval of a second or more; `minutely`, to specify repeating periods based on an interval of a minute or more; `hourly`, to specify repeating periods based on an interval of an hour or more; `daily`, to specify repeating periods based on an interval of a day or more; `weekly`, to specify repeating periods based on an interval of a week or more; `monthly`, to specify repeating periods based on an interval of a month or more; and `yearly`, to specify repeating periods based on an interval of a year or more. These values are not case-sensitive.

The `interval` parameter contains a positive integer representing how often the recurrence rule repeats. The default value is “1”, meaning every second for a `secondly` rule, every minute for a `minutely` rule, every

hour for an hourly rule, every day for a daily rule, every week for a weekly rule, every month for a monthly rule and every year for a yearly rule.

The **until** parameter defines an iCalendar COS DATE or DATE-TIME value which bounds the recurrence rule in an inclusive manner. If the value specified by **until** is synchronized with the specified recurrence, this date or date-time becomes the last instance of the recurrence. If specified as a date-time value, then it **MUST** be specified in an UTC time format. If not present, and the **count** parameter is not also present, the recurrence is considered to repeat forever.

The **count** parameter defines the number of occurrences at which to range-bound the recurrence. The **dtstart** parameter counts as the first occurrence. The **until** and **count** parameters **MUST NOT** occur in the same time output.

The **bysecond** parameter specifies a comma-separated list of seconds within a minute. Valid values are 0 to 59. The **byminute** parameter specifies a comma-separated list of minutes within an hour. Valid values are 0 to 59. The **byhour** parameter specifies a comma-separated list of hours of the day. Valid values are 0 to 23.

The **byday** parameter specifies a comma-separated list of days of the week. **MO** indicates Monday; **TU** indicates Tuesday; **WE** indicates Wednesday; **TH** indicates Thursday; **FR** indicates Friday; **SA** indicates Saturday; **SU** indicates Sunday. These values are not case-sensitive.

Each **byday** value can also be preceded by a positive (+n) or negative (-n) integer. If present, this indicates the nth occurrence of the specific day within the **monthly** or **yearly** recurrence. For example, within a **monthly** rule, +1MO (or simply 1MO) represents the first Monday within the month, whereas -1MO represents the last Monday of the month. If an integer modifier is not present, it means all days of this type within the specified frequency. For example, within a **monthly** rule, **MO** represents all Mondays within the month.

The **bymonthday** parameter specifies a comma-separated list of days of the month. Valid values are 1 to 31 or -31 to -1. For example, -10 represents the tenth to the last day of the month.

The **byyearday** parameter specifies a comma-separated list of days of the year. Valid values are 1 to 366 or -366 to -1. For example, -1 represents the last day of the year (December 31st) and -306 represents the 306th to the last day of the year (March 1st).

The **byweekno** parameter specifies a comma-separated list of ordinals specifying weeks of the year. Valid values are 1 to 53 or -53 to -1. This corresponds to weeks according to week numbering as defined in ISO 8601 [20]. A week is defined as a seven day period, starting on the day of the week defined to be the week start (see **wkst**). Week number one of the calendar year is the first week which contains at least four (4) days in that calendar year. This parameter is only valid for **yearly** rules. For example, 3 represents the third week of the year.

Note: Assuming a Monday week start, week 53 can only occur when Thursday is January 1 or if it is a leap year and Wednesday is January 1.

The **bymonth** parameter specifies a comma-separated list of months of the year. Valid values are 1 to 12.

The **wkst** parameter specifies the day on which the work week starts. Valid values are **MO**, **TU**, **WE**, **TH**, **FR**, **SA** and **SU**. This is significant when a **weekly** recurrence has an interval greater than 1, and a **byday** parameter is specified. This is also significant in a **yearly** recurrence when a **byweekno** parameter is specified. The default value is **MO**, following ISO 8601 [20].

The **bysetpos** parameter specifies a comma-separated list of values which corresponds to the nth occurrence within the set of events specified by the rule. Valid values are 1 to 366 or -366 to -1. It **MUST** only be used in conjunction with another **byxxx** parameter. For example “the last work day of the month” could be

represented as:

```
<time -timerange- freq="monthly" byday="MO,TU,WE,TH,FR"
  bysetpos="-1">
```

Each `bysetpos` value can include a positive (+n) or negative (-n) integer. If present, this indicates the nth occurrence of the specific occurrence within the set of events specified by the rule.

If `byxxx` parameter values are found which are beyond the available scope (ie, `bymonthday=``30``` in February), they are simply ignored.

`Byxxx` parameters modify the recurrence in some manner. `Byxxx` rule parts for a period of time which is the same or greater than the frequency generally reduce or limit the number of occurrences of the recurrence generated. For example, `freq=``daily`` bymonth=``1``` reduces the number of recurrence instances from all days (if the `bymonth` parameter is not present) to all days in January. `Byxxx` parameters for a period of time less than the frequency generally increase or expand the number of occurrences of the recurrence. For example, `freq=``yearly`` bymonth=``1,2``` increases the number of days within the yearly recurrence set from 1 (if `bymonth` parameter is not present) to 2.

If multiple `Byxxx` parameters are specified, then after evaluating the specified `freq` and `interval` parameters, the `Byxxx` parameters are applied to the current set of evaluated occurrences in the following order: `bymonth`, `byweekno`, `byyearday`, `bymonthday`, `byday`, `byhour`, `byminute`, `bysecond` and `bysetpos`; then `COUNT` and `UNTIL` are evaluated.

Here is an example of evaluating multiple `Byxxx` parameters.

```
<time dtstart="19970105T083000" duration="10M"
  freq="yearly" interval="2" bymonth="1" byday="SU"
  byhour="8,9" byminute="30">
```

First, the `interval="2"` would be applied to `freq="yearly"` to arrive at “every other year.” Then, `bymonth="1"` would be applied to arrive at “every January, every other year.” Then, `byday="SU"` would be applied to arrive at “every Sunday in January, every other year.” Then, `byhour="8,9"` would be applied to arrive at “every Sunday in January at 8 AM and 9 AM, every other year.” Then, `byminute="30"` would be applied to arrive at “every Sunday in January at 8:30 AM and 9:30 AM, every other year.” Then the second is derived from `dtstart` to end up in “every Sunday in January from 8:30:00 AM to 8:40:00 AM, and from and 9:30:00 AM to 9:40:00 AM, every other year.” Similarly, if the `byminute`, `byhour`, `byday`, `bymonthday` or `bymonth` parameter were missing, the appropriate minute, hour, day or month would have been retrieved from the `dtstart` parameter.

The iCalendar COS `RDATE`, `EXRULE` and `EXDATE` recurrence rules are not specifically mapped to components of the time-switch node. Equivalent functionality to the exception rules can be attained by using the ordering of switch rules to exclude times using earlier rules; equivalent functionality to the additional-date `RDATE` rules can be attained by using `sub` nodes (see Section 8) to link multiple outputs to the same subsequent node.

The `not-present` output is never true for a time switch. However, it MAY be included, to allow switch processing to be more regular.

#### 4.4.1 iCalendar differences and implementation issues

(This sub-sub-section is non-normative.)

The specification of recurring events in this section is identical (except for syntax and formatting issues) to that of RFC 2445 [8], with only one additional restriction. That one restriction is that consecutive instances of recurrence intervals may not overlap.

It was a matter of some debate, during the design of CPL, whether the entire iCalendar COS recurrence specification should be included in CPL, or whether only a subset should be included. It was eventually decided that compatibility between the two protocols was of primary importance. This imposes some additional implementation issues on implementors of CPL servers.

It does not appear to be possible to determine, in constant time, whether a given instant of time falls within one of the intervals defined by a full iCalendar COS recurrence. The primary concerns are as follows:

- The **count** parameter cannot be checked in constant running time, since it requires that the server enumerate all recurrences from **dtstart** to the present time, in order to determine whether the current recurrence satisfies the parameter. However, a server can expand a **count** parameter once, off-line, to determine the date of the last recurrence. This date can then be treated as a virtual **until** parameter for the server's internal processing.
- Similarly, the **bysetpos** parameter requires that the server enumerate all instances of the occurrence from the start of the current recurrence set until the present time. This requires somewhat more complex pre-processing, but generally, a single recurrence with a **bysetpos** parameter can be split up into several recurrences without them.
- Finally, constant running time of time switches also requires that a candidate starting time for a recurrence can be established quickly and uniquely, to check whether it satisfies the other restrictions. This requires that a recurrence's duration not be longer than its repetition interval, so that a given instant cannot fall within several consecutive potential repetitions of the recurrence. The restriction that consecutive intervals not overlap partially satisfies this condition, but does not fully ensure it. Again, to some extent pre-processing can help resolve this.

The algorithm given in Appendix A runs in constant time after these pre-processing steps.

Servers ought to check that recurrence rules do not create any absurd run-time or memory requirements, and reject those that do, just as they ought to check that CPL scripts in general are not absurdly large.

#### 4.5 Priority Switches

Priority switches allow a CPL script to make decisions based on the priority specified for the original call. They are summarized in Figure 8. They are dependent on the underlying signalling protocol.

Priority switches take no parameters.

The **priority** tag takes one of the three parameters **greater**, **less**, and **equal**. The values of these parameters are one of the following priorities: in decreasing order, **emergency**, **urgent**, **normal**, and **non-urgent**. These values are matched in a case-insensitive manner. Outputs with the **less** parameter are taken if the priority of the call is less than the priority given in the argument; and so forth.

If no priority is specified in a message, the priority is considered to be **normal**. If an unknown priority is specified in the call, it is considered to be equivalent to **normal** for the purposes of **greater** and **less** comparisons, but it is compared literally for **equal** comparisons.

Node:	priority-switch	
Outputs:	priority	Specific priority to match
Parameters:	None	
Output:	priority	
Parameters:	less	Match if priority is less than that specified
	greater	Match if priority is greater than that specified
	equal	Match if priority is equal to that specified

Figure 8: Syntax of the priority-switch node

Since every message has a priority, the **not-present** output is never true for a priority switch. However, it MAY be included, to allow switch processing to be more regular.

#### 4.5.1 Usage of priority-switch with SIP

The priority of a SIP message corresponds to the **Priority** header in the initial INVITE message.

## 5 Location Modifiers

The abstract location model of CPL is described in Section 2.3. The behavior of several of the signalling operations (defined in Section 6) is dependent on the current location set specified. Location nodes add or remove locations from the location set.

There are three types of location nodes defined. *Explicit locations* add literally-specified locations to the current location set; *location lookups* obtain locations from some outside source; and *location filters* remove locations from the set, based on some specified criteria.

### 5.1 Explicit Location

Explicit location nodes specify a location literally. Their syntax is described in Figure 9.

Explicit location nodes are dependent on the underlying signalling protocol.

Node:	location	
Outputs:	None	(Next node follows directly)
Next node:	Any node	
Parameters:	url	URL of address to add to location set
	priority	Priority of this location (0.0 – 1.0)
	clear	Whether to clear the location set before adding the new value

Figure 9: Syntax of the location node

Explicit location nodes have three node parameters. The mandatory `url` parameter's value is the URL of the address to add to the location set. Only one address may be specified per location node; multiple locations may be specified by cascading these nodes.

The optional `priority` parameter specifies a priority for the location. Its value is a floating-point number between 0.0 and 1.0. If it is not specified, the server SHOULD assume a default priority of 1.0. The optional `clear` parameter specifies whether the location set should be cleared before adding the new location to it. Its value can be "yes" or "no", with "no" as the default.

Basic location nodes have only one possible result, since there is no way that they can fail. (If a basic location node specifies a location which isn't supported by the underlying signalling protocol, the script server SHOULD detect this and report it to the user at the time the script is submitted.) Therefore, their XML representations do not have explicit output tags; the `<location>` tag directly contains another node.

### 5.1.1 Usage of location with SIP

All SIP locations are represented as URLs, so the locations specified in `location` tags are interpreted directly.

## 5.2 Location Lookup

Locations can also be specified up through external means, through the use of location lookups. The syntax of these tags is given in Figure 10.

Location lookup is dependent on the underlying signalling protocol.

Node:	<code>lookup</code>	
Outputs:	<code>success</code>	Next node if lookup was successful
	<code>notfound</code>	Next node if lookup found no addresses
	<code>failure</code>	Next node if lookup failed
Parameters:	<code>source</code>	Source of the lookup
	<code>timeout</code>	Time to try before giving up on the lookup
	<code>clear</code>	Whether to clear the location set before adding the new values
Output:	<code>success</code>	
Parameters:	<code>none</code>	
Output:	<code>notfound</code>	
Parameters:	<code>none</code>	
Output:	<code>failure</code>	
Parameters:	<code>none</code>	

Figure 10: Syntax of the `lookup` node

Location lookup nodes have one mandatory parameter and two optional parameters. The mandatory parameter is `source`, the source of the lookup. This can either be a URI, or a non-URI value. If the value of `source` is a URI, it indicates a location which the CPL server can query to obtain an object with the

`text/uri-list` media type (see the IANA registration of this type, which also appears in RFC 2483 [10]). The query is performed verbatim, with no additional information (such as URI parameters) added. The server adds the locations contained in this object to the location set.

CPL servers MAY refuse to allow URI-based sources for location queries for some or all URI schemes. In this case, they SHOULD reject the script at script upload time.

There has been discussion of having CPL servers add URI parameters to the location request, so that (for instance) CGI scripts could be used to resolve them. However, the consensus was that this should be a CPL extension, not a part of the base specification.

Non-URL sources indicate a source not specified by a URL which the server can query for addresses to add to the location set. The only non-URL source currently defined is `registration`, which specifies all the locations currently registered with the server.

The `lookup` node also has two optional parameters. The `timeout` parameter specifies the time, as a positive integer number of seconds, the script is willing to wait for the lookup to be performed. If this is not specified, its default value is 30. The `clear` parameter specifies whether the location set should be cleared before the new locations are added.

Lookup has three outputs: `success`, `notfound`, and `failure`. `Notfound` is taken if the lookup process succeeded but did not find any locations; `failure` is taken if the lookup failed for some reason, including that specified timeout was exceeded. If a given output is not present, script execution terminates and the default behavior is performed.

### 5.2.1 Usage of lookup with SIP

For SIP, the `registration` lookup source corresponds to the locations registered with the server using `REGISTER` messages.

## 5.3 Location Removal

A CPL script can also remove locations from the location set, through the use of the `remove-location` node. The syntax of this node is defined in Figure 11.

The meaning of this node is dependent on the underlying signalling protocol.

Node:	<code>remove-location</code>	
Outputs:	None	(Next node follows directly)
Next node:	Any node	
Parameters:	<code>location</code>	Location to remove

Figure 11: Syntax of the `remove-location` node

A `remove-location` node removes locations from the location set. It is primarily useful following a `lookup` node. An example of this is given in Section 12.8.

The `remove-location` node has one optional parameter. The parameter `location` gives the URL (or a signalling-protocol-dependent URL pattern) of location or locations to be removed from the set. If this parameter is not given, all locations are removed from the set.

The `remove-location` node has no explicit output tags. In the XML syntax, the XML `remove-location` tag directly encloses the next node's tag.

### 5.3.1 Usage of remove-location with SIP

The location specified in the location parameter of the remove-location node is matched against the location set using the standard rules for SIP URI matching (as are used, e.g., to match Contact addresses when refreshing registrations).

## 6 Signalling Operations

Signalling operation nodes cause signalling events in the underlying signalling protocol. Three signalling operations are defined: “proxy,” “redirect,” and “reject.”

### 6.1 Proxy

Proxy causes the triggering call to be forwarded on to the currently specified set of locations. The syntax of the proxy node is given in Figure 12.

The specific signalling events invoked by the proxy node are signalling-protocol-dependent, though the general concept should apply to any signalling protocol.

After a proxy operation has completed, the CPL server chooses the “best” response to the call attempt, as defined by the signalling protocol or the server’s administrative configuration rules.

If the call attempt was successful, CPL execution terminates and the server proceeds to its default behavior (normally, to allow the call to be set up). Otherwise, the next node corresponding to one of the proxy node’s outputs is taken. The busy output is followed if the call was busy; noanswer is followed if the call was not answered before the timeout parameter expired; redirection is followed if the call was redirected; and failure is followed if the call setup failed for any other reason.

If one of the conditions above is true, but the corresponding output was not specified, the default output of the proxy node is followed instead. If there is also no default node specified, CPL execution terminates and the server returns to its default behavior (normally, to forward the best response upstream to the originator).

Note: CPL extensions to allow in-call or end-of-call operations will require an additional output, such as success, to be added.

If no locations were present in the set, or if the only locations in the set were locations to which the server cannot proxy a call (for example, “http” URLs), the failure output is taken.

Proxy has three optional parameters. The timeout parameter specifies the time, as a positive integer number of seconds, to wait for the call to be completed or rejected; after this time has elapsed, the call attempt is terminated and the noanswer branch is taken. If this parameter is not specified, the default value is 20 seconds if the proxy node has a noanswer or default output specified; otherwise the server SHOULD allow the call to ring for a reasonably long period of time (to the maximum extent that server policy allows).

The second optional parameter is recurse, which can take two values, yes or no. This specifies whether the server should automatically attempt to place further call attempts to telephony addresses in redirection responses that were returned from the initial server. Note that if the value of recurse is yes, the redirection output to the script is never taken. In this case this output SHOULD NOT be present. The default value of this parameter is yes.

The third optional parameter is ordering. This can have three possible values: parallel, sequential, and first-only. This parameter specifies in what order the locations of the location set should be tried. Parallel asks that they all be tried simultaneously; sequential asks that the one with the highest priority be tried

Node:	proxy	
Outputs:	busy	Next node if call attempt returned “busy”
	noanswer	Next node if call attempt was not answered before timeout
	redirection	Next node if call attempt was redirected
	failure	Next node if call attempt failed
	default	Default next node for unspecified outputs
Parameters:	timeout	Time to try before giving up on the call attempt
	recurse	Whether to recursively look up redirections
	ordering	What order to try the location set in.
Output:	busy	
Parameters:	none	
Output:	noanswer	
Parameters:	none	
Output:	redirection	
Parameters:	none	
Output:	failure	
Parameters:	none	
Output:	default	
Parameters:	none	

Figure 12: Syntax of the proxy node

first, the one with the next-highest priority second, and so forth, until one succeeds or the set is exhausted. First-only instructs the server to try only the highest-priority address in the set, and then follow one of the outputs. The priority of locations in a set is determined by server policy, though CPL servers SHOULD honor the priority parameter of the location tag. The default value of this parameter is **parallel**.

Once a proxy operation completes, if control is passed on to other nodes, all locations which have been used are cleared from the location set. That is, the location set is emptied of proxyable locations if the ordering was **parallel** or **sequential**; the highest-priority item in the set is removed from the set if ordering was **first-only**. (In all cases, non-proxyable locations such as “http” URIs remain.) In the case of a redirection output, the new addresses to which the call was redirected are then added to the location set.

### 6.1.1 Usage of proxy with SIP

For SIP, the best response to a proxy node is determined by the algorithm of the SIP specification. The node’s outputs correspond to the following events:

**busy** A 486 or 600 response was the best response received to the call request.

**redirection** A 3xx response was the best response received to the call request.

**failure** Any other 4xx, 5xx, or 6xx response was the best response received to the call request.

**no-answer** No final response was received to the call request before the timeout expired.

SIP servers SHOULD honor the **q** parameter of SIP registrations when determining location priority. ■

## 6.2 Redirect

Redirect causes the server to direct the calling party to attempt to place its call to the currently specified set of locations. The syntax of this node is specified in Figure 13.

The specific behavior the redirect node invokes is dependent on the underlying signalling protocol involved, though its semantics are generally applicable.

Node:	<b>redirect</b>	
Outputs:	None	(No node may follow)
Next node:	None	
Parameters:	<b>permanent</b>	Whether the redirection should be considered permanent

Figure 13: Syntax of the **redirect** node

Redirect immediately terminates execution of the CPL script, so this node has no outputs and no next node. It has one parameter, **permanent**, which specifies whether the result returned should indicate that this is a permanent redirection. The value of this parameter is either “yes” or “no” and its default value is “no.”

### 6.2.1 Usage of **redirect** with SIP

The SIP server SHOULD send a 3xx class response to a call request upon executing a **redirect** tag. If **permanent** was **yes**, the server SHOULD send the response “301” (Moved permanently); otherwise it SHOULD send “302” (Moved temporarily).

## 6.3 Reject

Reject nodes cause the server to reject the call attempt. Their syntax is given in Figure 14. The specific behavior they invoke is dependent on the underlying signalling protocol involved, though their semantics are generally applicable.

A reject node immediately terminates the execution of a CPL script, so this node has no outputs and no next node.

This node has two arguments: **status** and **reason**. The **status** argument is required, and can take one of the values **busy**, **notfound**, **reject**, and **error**, or a signalling-protocol-defined status.

The **reason** argument optionally allows the script to specify a reason for the rejection.

```
Node: reject
Outputs: None (No node may follow)
Next node: None
Parameters: status Status code to return
           reason Reason phrase to return
```

Figure 14: Syntax of the `reject` node

### 6.3.1 Usage of `reject` with SIP

Servers which implement SIP SHOULD also allow the `status` field to be a numeric argument corresponding to a SIP status in the 4xx, 5xx, or 6xx range.

They SHOULD send the “reason” parameter in the SIP reason phrase.

A suggested mapping of the named statuses is as follows. Servers MAY use a different mapping, though similar semantics SHOULD be preserved.

**busy:** 486 Busy Here

**notfound:** 404 Not Found

**reject:** 603 Decline

**error:** 500 Internal Server Error

## 7 Non-signalling Operations

In addition to the signalling operations, CPL defines several operations which do not affect and are not dependent on the telephony signalling protocol.

### 7.1 Mail

The mail node causes the server to notify a user of the status of the CPL script through electronic mail. Its syntax is given in Figure 15.

```
Node: mail
Outputs: None (Next node follows directly)
Next node: Any node
Parameters: url Mailto url to which the mail should be sent
```

Figure 15: Syntax of the `mail` node

The mail node takes one argument: a `mailto` URL giving the address, and any additional desired parameters, of the mail to be sent. The server sends the message containing the content to the given url; it SHOULD also include other status information about the original call request and the CPL script at the time of the notification.

Using a full `mailto` URL rather than just an e-mail address allows additional e-mail headers to be specified, such as `<mail url="mailto:jones@example.com?subject=Lookup%20failed" />`.

A mail node has only one possible result, since failure of e-mail delivery cannot reliably be known in real-time. Therefore, its XML representation does not have output tags: the `<mail>` tag directly contains another node tag.

Note that the syntax of XML requires that ampersand characters, “&”, which are used as parameter separators in `mailto` URLs, be quoted as “&#amp;#x26;” inside parameter values (see Section C.12 of the XML specification [2]).

### 7.1.1 Suggested Content of Mailed Information

This section presents suggested guidelines for the mail sent as a result of the `mail` node, for requests triggered by SIP. The message mailed (triggered by any protocol) SHOULD contain all this information, but servers MAY elect to use a different format.

1. If the `mailto` URI did not specify a subject header, the subject of the e-mail is “[CPL]” followed by the subject header of the SIP request. If the URI specified a subject header, it is used instead.
2. The `From` field of the e-mail is set to a CPL server configured address, overriding any `From` field in the `mailto` URI.
3. Any `Reply-To` header in the URI is honored. If none is given, then an e-mail-ized version of the origin field of the request is used, if possible (e.g., a SIP `From` header with a `sip:` URI would be converted to an e-mail address by stripping the URI scheme).
4. If the `mailto` URI specifies a body, it is used. If none was specified, the body SHOULD contain at least the identity of the caller (both the caller’s display name and address), the date and time of day, the call subject, and if available, the call priority.

The server SHOULD honor the user’s requested languages, and send the mail notification using an appropriate language and character set.

## 7.2 Log

The `Log` node causes the server to log information about the call to non-volatile storage. Its syntax is specified in Figure 16.

```

Node:    log
Outputs: None      (Next node follows directly)
Next node: Any node
Parameters: name    Name of the log file to use
           comment  Comment to be placed in log file

```

Figure 16: Syntax of the `log` node

`Log` takes two arguments, both optional: `name`, which specifies the name of the log, and `comment`, which gives a comment about the information being logged. Servers SHOULD also include other information

in the log, such as the time of the logged event, information that triggered the call to be logged, and so forth. Logs are specific to the owner of the script which logged the event. If the `name` parameter is not given, the event is logged to a standard, server-defined log file for the script owner. This specification does not define how users may retrieve their logs from the server.

The name of a log is a logical name only, and does not necessarily correspond to any physical file on the server. The interpretation of the log file name is server defined, as is a mechanism to access these logs. The CPL server **SHOULD NOT** directly map log names uninterpreted onto local file names, for security reasons, lest a security-critical file be overwritten.

A correctly operating CPL server **SHOULD NOT** ever allow the `log` event to fail. As such, log nodes can have only one possible result, and their XML representation does not have explicit output tags. A CPL `<log>` tag directly contains another node tag.

## 8 Subactions

XML syntax defines a tree. To allow more general call flow diagrams, and to allow script re-use and modularity, we define subactions.

Two tags are defined for subactions: subaction definitions and subaction references. Their syntax is given in Figure 17.

Tag:	<b>subaction</b>	
Subtags:	Any node	
Parameters:	<b>id</b>	Name of this subaction
Pseudo-node:	<b>sub</b>	
Outputs:	None in XML tree	
Parameters:	<b>ref</b>	Name of subaction to execute

Figure 17: Syntax of subactions and `sub` pseudo-nodes

Subactions are defined through `subaction` tags. These tags are placed in CPL after any ancillary information (see Section 9) but before any top-level tags. They take one argument: `id`, a token indicating a script-chosen name for the subaction. The `id` value for every `subaction` tag in a script **MUST** be unique within that script.

Subactions are called from `sub` tags. The `sub` tag is a “pseudo-node”: it can be used anywhere in a CPL action that a true node could be used. It takes one parameter, `ref`, the name of the subaction to be called. The `sub` tag contains no outputs of its own; control instead passes to the subaction.

References to subactions **MUST** refer to subactions defined before the current action. A `sub` tag **MUST NOT** refer to the action which it appears in, or to any action defined later in the CPL script. Top-level actions cannot be called from `sub` tags, or through any other means. Script servers **MUST** verify at the time the script is submitted that no `sub` node refers to any subaction which is not its proper predecessor.

Allowing only back-references of subs forbids any sort of recursion. Recursion would introduce the possibility of non-terminating or non-decidable CPL scripts, a possibility our requirements specifically excluded.

Every `sub` **MUST** refer to a subaction ID defined within the same CPL script. No external links are permitted.

Subaction IDs are case sensitive.

If any subsequent version or extension defines external linkages, it should probably use a different tag, perhaps XLink [21]. Ensuring termination in the presence of external links is a difficult problem.

## 9 Ancillary Information

No ancillary information is defined in the base CPL specification. If ancillary information, not part of any operation, is found to be necessary for a CPL extension, it SHOULD be placed within this tag.

The (trivial) definition of the ancillary information tag is given in Figure 18.

It may be useful to include timezone definitions inside CPL scripts directly, rather than referencing them externally with tzid and tzurl parameters. If it is, an extension could be defined to include them here.

```
Tag:    ancillary
Parameters:  None
Subtags:  None
```

Figure 18: Syntax of the ancillary tag

## 10 Default Behavior

When a CPL node reaches an unspecified output, either because the output tag is not present, or because the tag is present but does not contain a node, the CPL server's behavior is dependent on the current state of script execution. This section gives the operations that should be taken in each case.

**no location modifications or signalling operations performed, location set empty:** Look up the user's location through whatever mechanism the server would use if no CPL script were in effect. Proxy, redirect, or send a rejection message, using whatever policy the server would use in the absence of a CPL script.

**no location modifications or signalling operations performed, location set non-empty:** (This can only happen for outgoing calls.) Proxy the call to the addresses in the location set.

**location modifications performed, no signalling operations:** Proxy or redirect the call, whichever is the server's standard policy, to the addresses in the current location set. If the location set is empty, return notfound rejection.

**noanswer output of proxy, no timeout given:** (This is a special case.) If the noanswer output of a proxy node is unspecified, and no timeout parameter was given to the proxy node, the call should be allowed to ring for the maximum length of time allowed by the server (or the request, if the request specified a timeout).

**proxy operation previously taken:** Return whatever the "best" response is of all accumulated responses to the call to this point, according to the rules of the underlying signalling protocol.

## 11 CPL Extensions

Servers MAY support additional CPL features beyond those listed in this document. Some of the extensions which have been suggested are a means of querying how a call has been authenticated; richer control over H.323 addressing; end-system or administrator-specific features; regular-expression matching for strings and addresses; and mid-call or end-of-call controls.

CPL extensions are indicated by XML namespaces [11]. Every extension MUST have an appropriate XML namespace assigned to it. All XML tags and attributes that are part of the extension MUST be appropriately qualified so as to place them within that namespace.

Tags or attributes in a CPL script which are in the global namespace (i.e., not associated with any namespace) are equivalent to tags and attributes in the CPL namespace "urn:ietf:params:xml:ns:cpl".

A CPL script SHOULD NOT specify any namespaces it does not use. For compatibility with non-namespace-aware parsers, a CPL script MAY omit the base CPL namespace for a script which does not use any extensions.

A CPL server MUST reject any script which contains a reference to a namespace which it does not understand. It MUST reject any script which contains an extension tag or attribute which is not qualified to be in an appropriate namespace.

A syntax such as

```
<extension-switch>
  <extension has="http://www.example.com/foo">
    [extended things]
  </extension>
  <otherwise>
    [non-extended things]
  </otherwise>
</extension-switch>
```

was suggested as an alternate way of handling extensions. This would allow scripts to be uploaded to a server without requiring a script author to somehow determine which extensions a server supports. However, experience developing other languages, notably Sieve [22], was that this added excessive complexity to languages. The extension-switch tag could, of course, itself be defined in a CPL extension.

In the XML schema of CPL, we introduce three abstract elements, namely 'toplevelaction', 'switch', and 'action', which accordingly have the abstract type 'TopLevelActionType', 'SwitchType', and 'ActionType'. Any top-level action in a CPL extension MUST be defined as the substitutionGroup of the abstract 'toplevelaction' element, and has the type extended from the 'TopLevelActionType'. Any switch in a CPL extension MUST be defined as the substitutionGroup of the abstract 'switch' element, and has the type extended from the 'SwitchType'. Any action in a CPL extension MUST be defined as the substitutionGroup of the abstract 'action' element, and has the type extended from the 'ActionType'.

## 12 Examples

### 12.1 Example: Call Redirect Unconditional

The script in Figure 19 is a simple script which redirects all calls to a single fixed location.

```
<?xml version="1.0" encoding="UTF-8"?>
<cpl xmlns="urn:ietf:params:xml:ns:cpl"
  xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
  xsi:schemaLocation="urn:ietf:params:xml:ns:cpl cpl.xsd ">
  <incoming>
    <location url="sip:smith@phone.example.com">
      <redirect/>
    </location>
  </incoming>
</cpl>
```

Figure 19: Example Script: Call Redirect Unconditional

## 12.2 Example: Call Forward Busy/No Answer

The script in Figure 20 illustrates some more complex behavior. We see an initial proxy attempt to one address, with further operations if that fails. We also see how several outputs take the same action subtree, through the use of subactions.

```
<?xml version="1.0" encoding="UTF-8"?>
<cpl xmlns="urn:ietf:params:xml:ns:cpl"
  xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
  xsi:schemaLocation="urn:ietf:params:xml:ns:cpl cpl.xsd ">
  <subaction id="voicemail">
    <location url="sip:jones@voicemail.example.com">
      <proxy/>
    </location>
  </subaction>
  <incoming>
    <location url="sip:jones@jonespc.example.com">
      <proxy timeout="8">
        <busy>
          <sub ref="voicemail"/>
        </busy>
        <noanswer>
          <sub ref="voicemail"/>
        </noanswer>
      </proxy>
    </location>
  </incoming>
</cpl>
```

Figure 20: Example Script: Call Forward Busy/No Answer

### 12.3 Example: Call Forward: Redirect and Default

The script in Figure 21 illustrates further proxy behavior. The server initially tries to proxy to a single address. If this attempt is redirected, a new redirection is generated using the locations returned. In all other failure cases for the proxy node, a default operation — forwarding to voicemail — is performed.

```
<?xml version="1.0" encoding="UTF-8"?>
<cpl xmlns="urn:ietf:params:xml:ns:cpl"
  xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
  xsi:schemaLocation="urn:ietf:params:xml:ns:cpl cpl.xsd ">
  <incoming>
    <location url="sip:jones@jonespc.example.com">
      <proxy>
        <redirection>
          <redirect/>
        </redirection>
        <default>
          <location url="sip:jones@voicemail.example.com">
            <proxy/>
          </location>
        </default>
      </proxy>
    </location>
  </incoming>
</cpl>
```

Figure 21: Example Script: Call Forward: Redirect and Default

### 12.4 Example: Call Screening

The script in Figure 22 illustrates address switches and call rejection, in the form of a call screening script. Note also that because the address-switch lacks an **otherwise** clause, if the initial pattern did not match, the script does not define any operations. The server therefore proceeds with its default behavior, which would presumably be to contact the user.

### 12.5 Example: Priority and Language Routing

The script in Figure 23 illustrates service selection based on a call's priority value and language settings. If the call request had a priority of "urgent" or higher, the default script behavior is performed. Otherwise, the language field is checked for the language "es" (Spanish). If it is present, the call is proxied to a Spanish-speaking operator; other calls are proxied to an English-speaking operator.

### 12.6 Example: Outgoing Call Screening

The script in Figure 24 illustrates a script filtering outgoing calls, in the form of a script which prevent 1-900 (premium) calls from being placed. This script also illustrates subdomain matching.

```
<?xml version="1.0" encoding="UTF-8"?>
<cpl xmlns="urn:ietf:params:xml:ns:cpl"
  xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
  xsi:schemaLocation="urn:ietf:params:xml:ns:cpl cpl.xsd ">
  <incoming>
    <address-switch field="origin" subfield="user">
      <address is="anonymous">
        <reject status="reject" reason="I reject anonymous calls"/>
      </address>
    </address-switch>
  </incoming>
</cpl>
```

Figure 22: Example Script: Call Screening

```
<?xml version="1.0" encoding="UTF-8"?>
<cpl xmlns="urn:ietf:params:xml:ns:cpl"
  xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
  xsi:schemaLocation="urn:ietf:params:xml:ns:cpl cpl.xsd ">
  <incoming>
    <priority-switch>
      <priority greater="urgent"/>
      <otherwise>
        <language-switch>
          <language matches="es">
            <location url="sip:spanish@operator.example.com">
              <proxy/>
            </location>
          </language>
          <otherwise>
            <location url="sip:english@operator.example.com">
              <proxy/>
            </location>
          </otherwise>
        </language-switch>
      </otherwise>
    </priority-switch>
  </incoming>
</cpl>
```

Figure 23: Example Script: Priority and Language Routing

## 12.7 Example: Time-of-day Routing

Figure 25 illustrates time-based conditions and timezones.

```
<?xml version="1.0" encoding="UTF-8"?>
<cpl xmlns="urn:ietf:params:xml:ns:cpl"
  xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
  xsi:schemaLocation="urn:ietf:params:xml:ns:cpl cpl.xsd ">
  <outgoing>
    <address-switch field="original-destination" subfield="tel">
      <address subdomain-of="1900">
        <reject status="reject"
          reason="Not allowed to make 1-900 calls."/>
      </address>
    </address-switch>
  </outgoing>
</cpl>
```

Figure 24: Example Script: Outgoing Call Screening

```
<?xml version="1.0" encoding="UTF-8"?>
<cpl xmlns="urn:ietf:params:xml:ns:cpl"
  xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
  xsi:schemaLocation="urn:ietf:params:xml:ns:cpl cpl.xsd ">
  <incoming>
    <time-switch tzid="America/New_York"
      tzurl="http://zones.example.com/tz/America/New_York">
      <time dtstart="20000703T090000" duration="PT8H" freq="weekly"
        byday="MO,TU,WE,TH,FR">
        <lookup source="registration">
          <success>
            <proxy/>
          </success>
        </lookup>
      </time>
    <otherwise>
      <location url="sip:jones@voicemail.example.com">
        <proxy/>
      </location>
    </otherwise>
  </time-switch>
</incoming>
</cpl>
```

Figure 25: Example Script: Time-of-day Routing

## 12.8 Example: Location Filtering

Figure 26 illustrates filtering operations on the location set. In this example, we assume that version 0.9beta2 of the “Inadequate Software SIP User Agent” mis-implements some features, and so we must work around

its problems. We know that it cannot talk successfully to one particular mobile device we may have registered, so we remove that location from the location set. Once this operation has been completed, call setup is allowed to proceed normally.

```
<?xml version="1.0" encoding="UTF-8"?>
<cpl xmlns="urn:ietf:params:xml:ns:cpl"
  xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
  xsi:schemaLocation="urn:ietf:params:xml:ns:cpl cpl.xsd ">
  <incoming>
    <string-switch field="user-agent">
      <string is="Inadequate Software SIP User Agent/0.9beta2">
        <lookup source="registration">
          <success>
            <remove-location location="sip:me@mobile.provider.net">
              <proxy/>
            </remove-location>
          </success>
        </lookup>
      </string>
    </string-switch>
  </incoming>
</cpl>
```

Figure 26: Example Script: Location Filtering

## 12.9 Example: Non-signalling Operations

Figure 27 illustrates non-signalling operations; in particular, alerting a user by electronic mail if the lookup server failed. The primary motivation for having the `mail` node is to allow this sort of out-of-band notification of error conditions, as the user might otherwise be unaware of any problem.

## 12.10 Example: Hypothetical Extensions

The example in Figure 12.10 shows a hypothetical extension which implements distinctive ringing. The XML namespace `“http://www.example.com/distinctive-ring”` specifies a new node named `ring`.

The example in Figure 29 implements a hypothetical new attribute for address switches, to allow regular-expression matches. It defines a new attribute `regex` for the standard `address` node.

## 12.11 Example: A Complex Example

Finally, Figure 30 is a complex example which shows the sort of sophisticated behavior which can be achieved by combining CPL nodes. In this case, the user attempts to have his calls reach his desk; if he does not answer within a small amount of time, calls from his boss are forwarded to his mobile phone, and all other calls are directed to voicemail. If the call setup failed, no operation is specified, so the server's default behavior is performed.

```
<?xml version="1.0" encoding="UTF-8"?>
<cpl xmlns="urn:ietf:params:xml:ns:cpl"
  xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
  xsi:schemaLocation="urn:ietf:params:xml:ns:cpl cpl.xsd ">
  <incoming>
    <lookup
      source="http://www.example.com/cgi-bin/locate.cgi?user=mary"
      timeout="8">
      <success>
        <proxy/>
      </success>
      <failure>
        <mail url="mailto:mary@example.com?subject=Lookup%20failed"/>
      </failure>
    </lookup>
  </incoming>
</cpl>
```

Figure 27: Example Script: Non-signalling Operations

```
<?xml version="1.0" encoding="UTF-8"?>
<xs:schema targetNamespace="http://www.example.com/distinctive-ring"
  xmlns="http://www.example.com/distinctive-ring"
  xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
  xmlns:xs="http://www.w3.org/2001/XMLSchema"
  xmlns:CPL="urn:ietf:params:xml:ns:cpl"
  elementFormDefault="qualified"
  attributeFormDefault="unqualified">

        </noanswer>
      </proxy>
    </location>
  </incoming>
</cpl>
```

Figure 30: Example Script: A Complex Example

## 13 Security Considerations

CPL is designed to allow services to be specified in a manner which prevents potentially hostile or mis-configured scripts from launching security attacks, including denial-of-service attacks. Because script run-time is strictly bounded by acyclicity, and because the number of possible script operations are strictly limited, scripts should not be able to inflict damage upon a CPL server.

Because scripts can direct users' telephone calls, the method by which scripts are transmitted from a client to a server **MUST** be strongly authenticated. Such a method is not specified in this document.

Script servers **SHOULD** allow server administrators to control the details of what CPL operations are permitted.

## 14 IANA Considerations

This document registers a new MIME type, `application/cpl+xml`, and a new URN per RFC 2141 [12], RFC 2648 [13], and RFC YYYY [14].

[Note to RFC Editor: please replace "YYYY" above with the RFC number of draft-mealling-iana-xmllns-registry, which is currently in the RFC Editor's queue, when it is published as an RFC.]

### 14.1 URN Sub-Namespace Registration for `urn:ietf:params:xml:ns:cpl`

**URI:** `urn:ietf:params:xml:ns:cpl`

**Registrant Contact:** Jonathan Lennox <[lennox@cs.columbia.edu](mailto:lennox@cs.columbia.edu)>  
 Xiaotao Wu <[xiaotaow@cs.columbia.edu](mailto:xiaotaow@cs.columbia.edu)>  
 Henning Schulzrinne <[hgs@cs.columbia.edu](mailto:hgs@cs.columbia.edu)>

**XML:** BEGIN  
 <?xml version="1.0"?>  
 <!DOCTYPE html PUBLIC "-//W3C//DTD XHTML Basic 1.0//EN"  
   "http://www.w3.org/TR/xhtml-basic/xhtml-basic10.dtd">  
 <html xmlns="http://www.w3.org/1999/xhtml">  
 <head>  
   <meta http-equiv="content-type"  
     content="text/html; charset=iso-8859-1"/>  
   <title>Call Processing Language Namespace</title>  
 </head>  
 <body>  
   <h1>Namespace for Call Processing Language</h1>  
   <h2>application/cpl+xml</h2>  
   <p><a href="[[[URL of published RFC]]]">RFCXXXX</a>.</p>  
 </body>  
 </html>  
 END

[Note to RFC Editor: please replace "[[[URL of published RFC]]]" above with the official URL of this RFC at [rfc-editor.org](http://rfc-editor.org), and "XXXX" above with the number of this RFC.]

## 14.2 MIME Registration

As an XML type, CPL's MIME registration conforms with "XML Media Types," RFC 3023 [15].

**MIME media type name:** application

**MIME subtype name:** cpl+xml

**Mandatory parameters:** none

**Optional parameters:** charset

As for application/xml in RFC 3023.

**Encoding considerations:** As for application/xml in RFC 3023.

**Security considerations:** See Section 13, and Section 10 of RFC 3023.

**Interoperability considerations:** Different CPL servers may use incompatible address types. However, all potential interoperability issues should be resolvable at the time a script is uploaded; there should be no interoperability issues which cannot be detected until runtime.

**Published specification:** This document.

**Applications which use this media type:** A number of Internet telephony servers, mostly using SIP. Specifically, the authors of this specification have implemented it in their SIP proxy server (part of the CINEMA project).

**Additional information: Magic number:** None

**File extension:** .cpl or .xml

**Macintosh file type code:** "TEXT"

**Person and e-mail address for further information:**

Jonathan Lennox <lennox@cs.columbia.edu>

Xiaotao Wu <xiaotaow@cs.columbia.edu>

Henning Schulzrinne <hgs@cs.columbia.edu>

**Intended usage:** COMMON

**Author/Change Controller:** The IETF.

## 15 Acknowledgments

This document was reviewed and commented upon by IETF IP Telephony Working Group. We specifically acknowledge the following people for their help:

The outgoing call screening script was written by Kenny Hom.

Paul E. Jones contributed greatly to the mappings of H.323 addresses.

The text of the time-switch section was taken (lightly modified) from RFC 2445 [8], by Frank Dawson and Derik Stenerson.

We drew a good deal of inspiration, notably the language's lack of Turing-completeness and the syntax of string matching, from the specification of Sieve [22], a language for user filtering of electronic mail messages.

Thomas F. La Porta and Jonathan Rosenberg had many useful discussions, contributions, and suggestions.

Richard Gumpertz performed a very useful last-minute technical and editorial review of the specification.

## A An Algorithm for Resolving Time Switches

The following algorithm determines whether a given instant falls within a repetition of a time-switch recurrence. If the pre-processing described in Section 4.4.1 has been done, it operates in constant time. Open-source Java code implementing this algorithm is available on the world wide web at <http://www.cs.columbia.edu/~lennox/Cal-Code/>.

This algorithm is believed to be correct, but this section is non-normative. Section 4.4, and RFC 2445 [8], are the definitive definitions of recurrences.

1. Compute the time of the call, in the timezone of the time switch.
2. If the call time is earlier than **dtstart**, fail **NOMATCH**.
3. If the call time is less than **duration** after **dtstart**, succeed **MATCH**.
4. Determine the smallest unit specified in a **byxxx** rule or by the **freq**. Call this the *Minimum Unit*. Determine the previous instant (before or equal to the call time) when all the time units smaller than the minimum unit are the same as those of **dtstart**. If the minimum unit is a second, this time is the same as the instant. If the minimum unit is a minute or an hour, the minutes or the minutes and hours, respectively, must be the same as **dtstart**. For all other minimum units, the time-of-day must be the same as **dtstart**. If the minimum unit is a week, the day-of-the-week must be the same as **dtstart**. If the minimum unit is a month, the day-of-the-month must be the same as **dtstart**. If the minimum unit is a year, the month and day-of-month must both be the same as **dtstart**. (Note that this means it may be necessary to roll back more than one minimum unit — if the minimum unit is a month, then some months do not have a 31st (or 30th or 29th) day; if the minimum unit is a year, then some years do not have a February 29th. In the Gregorian calendar, it is never necessary to roll back more than two months if the minimum unit is a month, or eight years if the minimum unit is a year. Between 1904 and 2096, it is never necessary to roll back more than four years — the eight-year rollback can only occur when the Gregorian calendar “skips” a leap year.

Call this instant the *Candidate Start Time*.

5. If the time between the candidate start time and the call time is more than the **duration**, fail **NOMATCH**.
6. If the candidate start time is later than the **until** parameter of the recurrence (or the virtual **until** computed off-line from **count**), fail **NOMATCH**.
7. Call the unit of the **freq** parameter of the recurrence the *Frequency Unit*. Determine the frequency unit enclosing the Candidate Start Time, and that enclosing **dtstart**. Calculate the number of frequency

units that have passed between these two times. If this is not a multiple of the `interval` parameter, fail **NOMATCH**.

8. For every `byxxx` rule, confirm that the candidate start time matches one of the options specified by that `byxxx` rule. If so, succeed **MATCH**.
9. Calculate a previous candidate start time. Repeat until the difference between the candidate start time and the call time is more than the duration. If no candidate start time has been validated, fail **NOMATCH**.

## B Suggested Usage of CPL with H.323

This appendix gives a suggested usage of CPL with H.323 [16]. Study Group 16 of the ITU, which developed H.323, is proposing to work on official CPL mappings for that protocol. This section is therefore not normative.

### B.1 Usage of address-switch with H.323

Address switches are specified in Section 4.1. This section specifies the mapping between H.323 messages and the fields and subfields of address-switches

For H.323, the `origin` address corresponds to the alias addresses in the `sourceAddress` field of the `Setup-UUIE` user-user information element, and to the Q.931 [23] information element "Calling party number." If both fields are present, or if multiple aliases addresses for `sourceAddress` are present, which one has priority is a matter of local server policy; the server **SHOULD** use the same resolution as it would use for routing decisions in this case. Similarly, the `destination` address corresponds to the alias addresses of the `destinationAddress` field, and to the Q.931 information element "Called party number."

The `original-destination` address corresponds to the "Redirecting number" Q.931 information element, if it is present; otherwise it is the same as the `destination` address.

The mapping of H.323 addresses into subfields depends on the type of the alias address. An additional subfield type, `alias-type`, is defined for H.323 servers, corresponding to the type of the address. Possible values are `dialedDigits`, `h323-ID`, `url-ID`, `transportID`, `email-ID`, `partyNumber`, `mobileUIM`, and `Q.931IE`. If future versions of the H.323 specification define additional types of alias addresses, those names **MAY** also be used.

In versions of H.323 prior to version 4, `dialedDigits` was known as `e164`. The two names **SHOULD** be treated as synonyms.

The value of the `address-type` subfield for H.323 messages is "h323" unless the alias type is `url-ID` and the URL scheme is something other than h323; in this case the `address-type` is the URL scheme, as specified in Section 4.1.1 for SIP.

An H.323-aware CPL server **SHOULD** map the address subfields from the primary alias used for routing. It **MAY** also map subfields from other aliases, if subfields in the primary address are not present.

The following mappings are used for H.323 alias types:

**dialedDigits, partyNumber, mobileUIM, and Q.931IE:** the `tel` and `user` subfields are the string of digits, as is the "entire-address" form. The `host` and `port` subfields are not present.

**url-ID:** the same mappings are used as for SIP, in Section 4.1.1.

**h323-ID:** the `user` field is the string of characters, as is the “entire-address” form. All other subfields are not present.

**email-ID:** the `user` and `host` subfields are set to the corresponding parts of the e-mail address. The `port` and `tel` subfields are not present. The “entire-address” form corresponds to the entire e-mail address.

**transportID:** if the `TransportAddress` is of type “ipAddress,” “ipSourceRoute,” or “ip6Address,” the `host` subfield is set to the “ip” element of the sequence, translated into the standard IPv4 or IPv6 textual representation, and the `port` subfield is set to the “port” element of the sequence represented in decimal. The `tel` and `user` fields are not present. The “entire-address” form is not defined. The representation and mapping of transport addresses is not defined for non-IP addresses.

H.323 version 4 [16] defines an “h323” URI scheme. This appendix defines a mapping for these URIs onto the CPL `address-switch` subfields, as given in Section 4.1. This definition is also available as RFC 3508 [24], which is an excerpt from the H.323 specification.

For h323 URIs, the `user`, `host`, and `port` subfields are set to the corresponding parts of the H.323 URL. The `tel` subfield is not present. The “entire-address” form corresponds to the entire URI.

This mapping MAY be used both for h323 URIs in an h323 `url-ID` address alias, and for h323 URIs in SIP messages.

## B.2 Usage of `string-switch` with H.323

For H.323, the `string-switch` node (see Section 4.2) is used as follows. The field `display` corresponds to the Q.931 information element of the same name, copied verbatim. The fields `subject`, `organization`, and `user-agent` are not used and are never present.

The `display` IE is conventionally used for Caller-ID purposes, so arguably it should be mapped to the `display` subfield of an `address-match` with the field originator. However, since a) it is a message-level information element, not an address-level one, and b) the Q.931 specification [23] says only that “[t]he purpose of the Display information element is to supply display information that may be displayed by the user,” it seems to be more appropriate to allow it to be matched in a `string-switch` instead.

## B.3 Usage of `language-switch` with H.323

The `language-ranges` for the `language-switch` switch are obtained from the H.323 UUIE language. The switch is not-present if the initial message did not contain this UUIE.

## B.4 Usage of `priority-switch` with H.323

All H.323 messages are considered to have priority `normal` for the purpose of a priority switch (see Section 4.5).

## B.5 Usage of `location` with H.323

Locations in explicit location nodes (Section 5.1) are specified as URLs. Therefore, all locations added in this manner are interpreted as being of alias type `url-ID` in H.323.

Specifications of other H.323 address alias types will require a CPL extension (see Section 11).

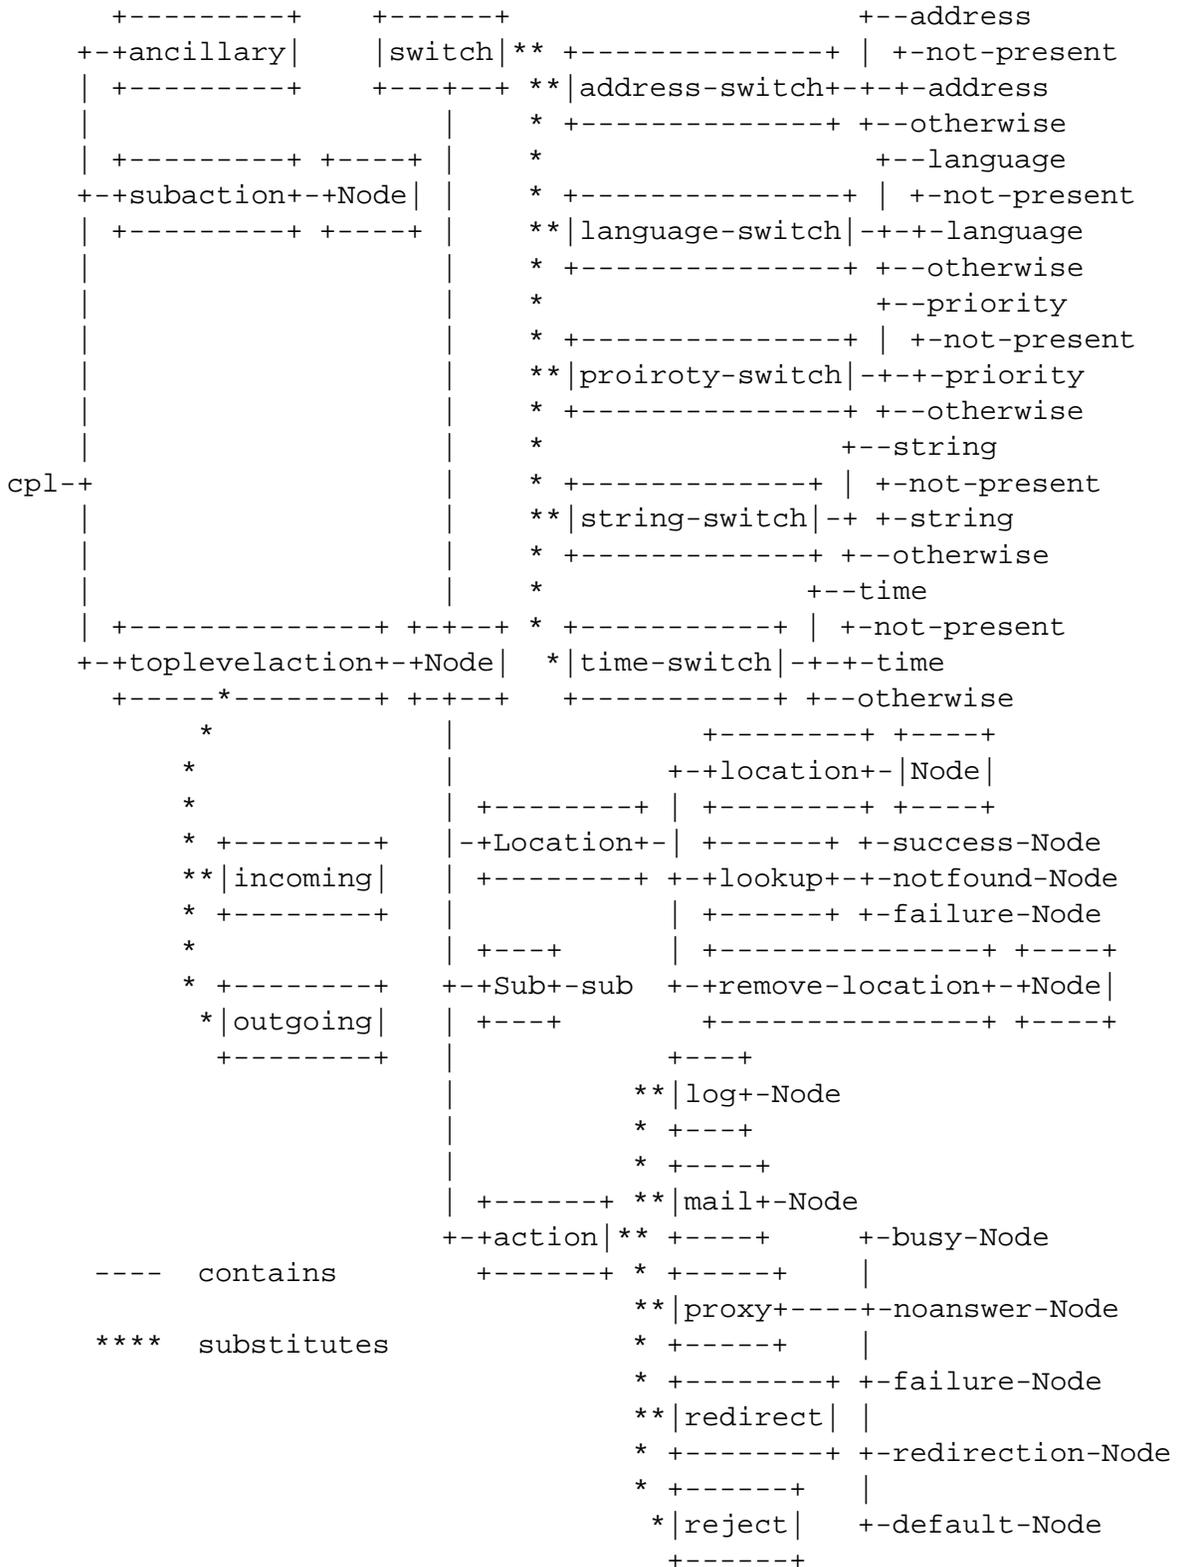

Figure 31: The structure of the XML schema for CPL

## B.6 Usage of lookup with H.323

For location lookup nodes (Section 5.2), the registration lookup source corresponds to the locations registered with the server using RAS messages.

## B.7 Usage of remove-location with H.323

Location removal nodes (Section 5.3) remove addresses with alias type url-ID using verbatim string matching on the URLs. If a tel URL is specified as the location, matching addresses (ignoring visual separators) with alias types dialedDigits (e164), partyNumber, mobileUIM, or Q.931IE are also removed. No mechanism is provided to remove other alias types.

# C The XML Schema for CPL

This section includes a full XML Schema describing the XML syntax of CPL. Every script submitted to a CPL server SHOULD comply with this XML Schema. When parsing scripts comply with the CPL DTD in earlier drafts, the DOCTYPE lines in the scripts should be ignored. Note that compliance with this schema is not a sufficient condition for correctness of a CPL script, as many of the conditions described in this specification are not expressible in schema syntax. Figure B.4 shows the structure of the schema. 'incoming' and 'outgoing' are defined as the substitutionGroup of the 'toplevelaction'. All the switches are defined as the substitutionGroup of the 'switch' element. All the actions are defined as the substitutionGroup of the 'action' element.

## D Changes from Earlier Versions

[Note to RFC Editor: please remove this appendix before publication as an RFC.]

### D.1 Changes from Draft -06

The changebars in the Postscript and PDF versions of this document indicate significant changes from this version.

- Added Xiaotao Wu as a co-author.
- Converted CPL DTD to CPL XML Schema.
- Dropped all features dependent on caller preferences and callee capabilities.
- Added an XML namespace URN `urn:ietf:params:xml:ns:cpl` and registration information for it.
- Separated normative and informative references.
- Updated some references; most notably, updated SIP reference to RFC 3261. Updated text to reflect changes in these references.
- Allowed servers more flexibility about recognizing SIP addresses as telephone numbers.

- Restored some text, in the definition of `interval`, accidentally omitted when sub-day recurrences were re-added in draft -05.
- Clarified the usages of `lookup` and `remove-location` with SIP, and `remove-location` with H.323.
- Updated address of the IPTel working group's mailing list.
- Improved wording, cleaned up formatting, and corrected typos.

## D.2 Changes from Draft -05

- Clarified that switch nodes are allowed to be degenerate — they can have no outputs, and they can have only an `otherwise` output.
- Clarified the (non-) usage of the special language-range `**`.
- Clarified that the Candidate Start Time can be equal to the call time.
- Modified the DTD to require that the `not-present` output appear only once.
- Added DTD entries for the `time-switch` attributes re-added in draft -05.
- Updated the reference to ISO 8601 to cite 8601:2000.
- Updated all H.323 references to cite H.323v4.
- Corrected some spelling errors.

## D.3 Changes from Draft -04

- Broke out language switches into their own switch node.
- Restored the full iCalendar COS recurrence specification. Added text describing the consequences of this for implementors, and expanded somewhat on the recurrence algorithm.
- Clarified when time zones are resolved.
- Spelled out “iCalendar” rather than abbreviating it “iCal.”
- Clarified some points about host and port matching.
- Whole-address matching in SIP uses the standard SIP URL-match rules.
- Specified that proxy and lookup timeouts are positive integer number of seconds.
- Specified that `subaction id` parameters must be unique.
- Corrected example scripts' namespace and DTD references indicating older drafts of this document.
- Deleted an unused subaction from the “Call Forward: Redirect and Default” example script.
- Made empty switches legal in the DTD.

- Made the legal values for the proxy ordering parameter explicit in the DTD.
- Made the `success` output of `lookup` optional in the DTD. It can trigger a default action, just like anything else.
- Clarified that the time-switch resolution algorithm is non-normative.
- Updated references to previously-unpublished RFCs, now published.
- Thanked Richard Gumpertz.

#### D.4 Changes from Draft -03

- Removed an obsolete reference to a usage in examples which wasn't actually used anywhere.
- Added forward references to `remove-location`, `mail` and `log`, as well as `location`, in the XML syntax as examples of nodes that don't have explicit output tags.
- Made the usage of some terminology more consistent: "output" vs. "next node"; "action" vs. "operation" vs. "behavior"; "sub-actions" and "subactions"; "other operations" and "non-call operations" and "non-signalling operations"; "meta-information" and "ancillary information."
- The `tel` subfield of addresses which come from sip URIs should have its visual separators stripped.
- The default value of the `priority` value of the `location` node is 1.0.
- Corrected the media type of a set of URIs to `text/uri-list`, and added a reference to it.
- Added some wording clarifying how URI-based lookup queries work.
- Corrected the syntax of `duration` parameter in the examples.
- Performed some pre-RFC textual cleanups (e.g. removing the reference to the Internet-Draft URL from the XML namespace identifier).
- Re-worded text in the description of the Ancillary tag which implied that information could be placed in that node in the base CPL specification. Clarified that the tag is for use by extensions only.
- Expunged some references to sub-daily recurrences which had accidentally been left in the text.
- Updated bibliography to refer to the latest versions of the cited documents.
- Fixed a number of typographical errors.

#### D.5 Changes from Draft -02

- Reduced time-switches from the full iCal recurrence to an iCal subset. Added an appendix giving an algorithm to resolve time-switches.
- Added the extension mechanism.

- Made explicit how each node is dependent on protocol handling. Separated out protocol-specific information — for SIP in subsections of the main text, for H.323 in a non-normative appendix.
- Clarified some address mapping rules for H.323.
- Corrected the name of the “Redirecting number” in Q.931.
- Clarified that address matching on the `password` subfield is case-sensitive.
- Added a recommendation that `tzid` labels follow the usage of the Olson database.
- Added the `priority` parameter to `location` nodes.
- Added the `default` output to the `proxy` node.
- Made the meaning of the `proxy` node’s outputs explicit.
- Added suggested content for the e-mail generated by `mail` nodes.
- Pointed out that “&” must be escaped in XML (this is relevant for `mailto` URIs).
- Pointed out that log names are logical names, and should not be interpreted as verbatim filenames.
- Added some examples.
- Clarified some wording.
- Fixed some typographical errors.

## D.6 Changes from Draft -01

- Completely re-wrote changes to time switches: they are now based on iCal rather than on `crontab`.
- Timezone references are now defined within time switches rather than in the ancillary section. The ancillary section is now empty, but still defined for future use. To facilitate this, an explicit `ancillary` tag was added.
- Added XML document type identifiers (the public identifier and the namespace), and MIME registration information.
- Clarified that the `not-present` output can appear anywhere in a switch.
- Re-wrote H.323 address mappings. Added the `alias-type` subfield for H.323 addresses.
- Added the `language` and `display` string switch fields.
- Clarified why useless `not-present` outputs can appear in time and priority switches.
- Added the `clear` parameter to `location` and `lookup` nodes. (It had been in the DTD previously, but not in the text.)
- Weakened support for non-validating scripts from `SHOULD` to `MAY`, to allow the use of validating XML parsers.

- Added redirection output of proxy nodes.
- Clarified some aspects of how proxy nodes handle the location set.
- Added permanent parameter of redirect nodes.
- Add example script for outgoing call screening (from Kenny Hom)
- Updated example scripts to use the public identifier.
- Add omitted tag to example script for call forward busy/no answer
- Clarified in introduction that this document mainly deals with servers.
- Updated reference to RFC 2824 now that it has been published.
- Added explanatory text to the introduction to types of nodes.
- Numerous minor clarifications and wording changes.
- Fixed copy-and-paste errors, typos.

#### **D.7 Changes from Draft -00**

- Added high-level structure; script doesn't just start at a first action.
- Added a section giving a high-level explanation of the location model.
- Added informal syntax specifications for each tag so people don't have to try to understand a DTD to figure out the syntax.
- Added subactions, replacing the old link tags. Links were far too reminiscent of gotos for everyone's taste.
- Added ancillary information section, and timezone support.
- Added not-present switch output.
- Added address switches.
- Made case-insensitive string matching locale-independent.
- Added priority switch.
- Deleted "Other switches" section. None seem to be needed.
- Unified url and source parameters of lookup.
- Added caller prefs to lookup.
- Added location filtering.
- Eliminated "clear" parameter of location setting. Instead, proxy "eats" locations it has used.

- Added recurse and ordering parameters to proxy.
- Added default value of timeout for proxy.
- Renamed response to reject.
- Changed notify to mail, and simplified it.
- Simplified log, eliminating its failure output.
- Added description of default actions at various times during script processing.
- Updated examples for these changes.
- Updated DTD to reflect new syntax.

## **E Authors' Addresses**

Jonathan Lennox
