Algorithms

al·go·rithm

a procedure for solving a mathematical problem (as of finding the greatest common divisor) in a finite number of steps that frequently involves repetition of an operation; broadly : a step-by-step procedure for solving a problem or accomplishing some end especially by a computer

Merriam-Webster

The Stored-Program Computer

John von Neumann, *First Draft of a Report on the EDVAC*, 1945.

“Since the device is primarily a computer, it will have to perform the elementary operations of arithmetics most frequently. [...] It is therefore reasonable that it should contain *specialized organs for just these operations*.

“If the device is to be [...] as nearly as possible all purpose, then a distinction must be made between the specific instructions given for and defining a particular problem, and the general control organs which see to it that these instructions [...] are carried out. The former must be *stored in some way* [...] the latter are represented by definite operating parts of the device.

“Any device which is to carry out long and complicated sequences of operations (specifically of calculations) *must have a considerable memory*.

Instruction Set Architecture (ISA)

ISA: The interface or contact between the hardware and the software

Rules about how to code and interpret machine instructions:

- ▶ Execution model (program counter)
- ▶ Operations (instructions)
- ▶ Data formats (sizes, addressing modes)
- ▶ Processor state (registers)
- ▶ Input and Output (memory, etc.)

Architecture vs. Microarchitecture

Architecture:
The interface the hardware presents to the software

Microarchitecture:
The detailed implementation of the architecture

MIPS

Microprocessor without Interlocked Pipeline Stages

MIPS developed at Stanford by Hennessey et al.
MIPS Computer Systems founded 1984. SGI acquired MIPS in 1992; spun it out in 1998 as MIPS Technologies.

RISC vs. CISC Architectures

MIPS is a Reduced Instruction Set Computer. Others include ARM, PowerPC, SPARC, HP-PA, and Alpha.

A Complex Instruction Set Computer (CISC) is one alternative. Intel's x86 is the most prominent example; also Motorola 68000 and DEC VAX.

RISC's underlying principles, due to Hennessy and Patterson:

- ▶ Simplicity favors regularity
- ▶ Make the common case fast
- ▶ Smaller is faster
- ▶ Good design demands good compromises

The GCD Algorithm

Euclid, *Elements*, 300 BC.

The greatest common divisor of two numbers does not change if the smaller is subtracted from the larger.

1. Call the two numbers a and b
2. If a and b are equal, stop: a is the greatest common divisor
3. Subtract the smaller from the larger
4. Repeat steps 2–4

The GCD Algorithm

Let's be a little more explicit:

1. Call the two numbers a and b
2. If a equals b , go to step 8
3. if a is less than b , go to step 6
4. Subtract b from a *$a > b$ here*
5. Go to step 2
6. Subtract a from b *$a < b$ here*
7. Go to step 2
8. Declare a the greatest common divisor
9. Go back to doing whatever you were doing before

Euclid's Algorithm in MIPS Assembly

gcd:

```
    beq  $a0, $a1, .L2    # if a = b, go to exit
    sgt  $v0, $a1, $a0    # Is b > a?
    bne  $v0, $zero, .L1  # Yes, goto .L1
```

```
    subu $a0, $a0, $a1    # Subtract b from a (b < a)
    b    gcd              # and repeat
```

.L1:

```
    subu $a1, $a1, $a0    # Subtract a from b (a < b)
    b    gcd              # and repeat
```

.L2:

```
    move $v0, $a0        # return a
    j    $ra             # Return to caller
```

Instructions

Control-transfer instructions

General-Purpose Registers

Name	Number	Usage	Preserved?
\$zero	0	Constant zero	
\$at	1	Reserved (assembler)	
\$v0-\$v1	2-3	Function result	
\$a0-\$a3	4-7	Function arguments	
\$t0-\$t7	8-15	Temporaries	
\$s0-\$s7	16-23	Saved	yes
\$t8-\$t9	24-25	Temporaries	
\$k0-\$k1	26-27	Reserved (OS)	
\$gp	28	Global pointer	yes
\$sp	29	Stack pointer	yes
\$fp	30	Frame pointer	yes
\$ra	31	Return address	yes

Each 32 bits wide

Only 0 truly behaves differently; usage is convention

Types of Instructions

Computational

Arithmetic and logical operations

Load and Store

Writing and reading data to/from memory

Jump and branch

Control transfer, often conditional

Miscellaneous

Everything else

Computational Instructions

Arithmetic		Shift Instructions	
add	Add	sll	Shift left logical
addu	Add unsigned	srl	Shift right logical
sub	Subtract	sra	Shift right arithmetic
subu	Subtract unsigned	sllv	Shift left logical variable
slt	Set on less than	srlv	Shift right logical variable
sltu	Set on less than unsigned	srav	Shift right arith. variable
and	AND	Multiply/Divide	
or	OR	mult	Multiply
xor	Exclusive OR	multu	Multiply unsigned
nor	NOR	div	Divide
Arithmetic (immediate)		divu	Divide unsigned
addi	Add immediate	mfhi	Move from HI
addiu	Add immediate unsigned	mthi	Move to HI
slti	Set on l. t. immediate	mflo	Move from LO
sltiu	Set on less than unsigned	mtlo	Move to LO
andi	AND immediate		
ori	OR immediate		
xori	Exclusive OR immediate		
lui	Load upper immediate		

Computational Instructions

Arithmetic, logical, and other computations. Example:

add \$t0, \$t1, \$t3

“Add the contents of registers \$t1 and \$t3; store the result in \$t0”

Register form:

operation R_D, R_S, R_T

“Perform *operation* on the contents of registers R_S and R_T ; store the result in R_D ”

Passes control to the next instruction in memory after running.

Arithmetic Instruction Example

a	b	c	f	g	h	i	j
<code>\$s0</code>	<code>\$s1</code>	<code>\$s2</code>	<code>\$s3</code>	<code>\$s4</code>	<code>\$s5</code>	<code>\$s6</code>	<code>\$s7</code>

```
a = b - c;          subu $s0, $s1, $s2
f = (g + h) - (i + j); addu $t0, $s4, $s5
                    addu $t1, $s6, $s7
                    subu $s3, $t0, $t1
```

“Signed” addition/subtraction (**add/sub**) throw an exception on a two’s-complement overflow; “Unsigned” variants (**addu/subu**) do not. Resulting bit patterns otherwise identical.

Bitwise Logical Operator Example

```
li    $t0, 0xFF00FF00 # "Load immediate"
li    $t1, 0xF0F0F0F0 # "Load immediate"

nor   $t2, $t0, $t1    # Puts 0x000F000F in $t2

li    $v0, 1           # print_int
move  $a0, $t2         # print contents of $t2
syscall
```

Immediate Computational Instructions

Example:

```
addiu $t0, $t1, 42
```

“Add the contents of register \$t1 and 42; store the result in register \$t0”

In general,

operation R_D, R_S, I

“Perform *operation* on the contents of register R_S and the signed 16-bit immediate I ; store the result in R_D ”
Thus, I can range from -32768 to 32767 .

32-Bit Constants and lui

It is easy to load a register with a constant from -32768 to 32767, e.g.,

```
ori $t0, $0, 42
```

Larger numbers use “load upper immediate,” which fills a register with a 16-bit immediate value followed by 16 zeros; an OR handily fills in the rest. E.g., Load \$t0 with 0xCODEFACE:

```
lui $t0, 0xCODE  
ori $t0, $t0, 0xFACE
```

The assembler automatically expands the **li** pseudo-instruction into such an instruction sequence

```
li $t1, 0xCAFE0B0E → lui $t1, 0xCAFE  
ori $t1, $t1, 0x0B0E
```

Multiplication and Division

Multiplication gives 64-bit result in two 32-bit registers: HI and LO. Division: LO has quotient; HI has remainder.

```
int multdiv(  
    int a,          // $a0  
    int b,          // $a1  
    unsigned c,    // $a2  
    unsigned d) // $a3  
{  
    a = a * b + c;  
    c = c * d + a;  
  
    a = a / c;  
    b = b % a;  
    c = c / d;  
    d = d % c;  
  
    return a + b + c + d;  
}
```

```
multdiv:  
    mult $a0,$a1      # a * b  
    mflo $t0  
    addu $a0,$t0,$a2 # a = a*b + c  
    mult $a2,$a3      # c * d  
    mflo $t1  
    addu $a2,$t1,$a0 # c = c*d + a  
    divu $a0,$a2      # a / c  
    mflo $a0          # a = a/c  
    div  $0,$a1,$a0   # b % a  
    mfhi $a1          # b = b%a  
    divu $a2,$a3      # c / d  
    mflo $a2          # c = c/d  
    addu $t2,$a0,$a1 # a + b  
    addu $t2,$t2,$a2 # (a+b) + c  
    divu $a3,$a2      # d % c  
    mfhi $a3          # d = d%c  
    addu $v0,$t2,$a3 # ((a+b)+c) + d  
    j    $ra
```

Shift Left

Shifting left amounts to multiplying by a power of two. Zeros are added to the least significant bits. The constant form explicitly specifies the number of bits to shift:

```
sll $a0, $a0, 1
```

The variable form takes the number of bits to shift from a register (mod 32):

```
sllv $a1, $a0, $t0
```

Shift Right Logical

The logical form of right shift adds 0's to the MSB.

```
srl $a0, $a0, 1
```

Shift Right Arithmetic

The “arithmetic” form of right shift sign-extends the word by copying the MSB.

```
sra $a0, $a0, 2
```

Set on Less Than

```
slt $t0, $t1, $t2
```

Set \$t0 to 1 if the contents of \$t1 < \$t2; 0 otherwise.
\$t1 and \$t2 are treated as 32-bit signed two's complement numbers.

```
int compare(int a,      // $a0
            int b,      // $a1
            unsigned c, // $a2
            unsigned d) // $a3
{
    int r = 0;          // $v0
    if (a < b) r += 42;
    if (c < d) r += 99;
    return r;
}
```

```
compare:
    move $v0, $zero
    slt  $t0, $a0, $a1
    beq  $t0, $zero, .L1
    addi $v0, $v0, 42
.L1:
    sltu $t0, $a2, $a3
    beq  $t0, $zero, .L2
    addi $v0, $v0, 99
.L2:
    j    $ra
```

Load and Store Instructions

Load/Store Instructions

lb	Load byte
lbu	Load byte unsigned
lh	Load halfword
lhu	Load halfword unsigned
lw	Load word
lwl	Load word left
lwr	Load word right
sb	Store byte
sh	Store halfword
sw	Store word
swl	Store word left
swr	Store word right

The MIPS is a load/store architecture: data must be moved into registers for computation.

Other architectures e.g., (x86) allow arithmetic directly on data in memory.

Memory on the MIPS

Memory is byte-addressed.
Each byte consists of eight bits:

7	6	5	4	3	2	1	0
---	---	---	---	---	---	---	---

Bytes have non-negative integer addresses. Byte addresses on the 32-bit MIPS processor are 32 bits; 64-bit processors usually have 64-bit addresses.

0:	7	6	5	4	3	2	1	0
1:	7	6	5	4	3	2	1	0
2:	7	6	5	4	3	2	1	0

⋮

$2^{32} - 1$:	7	6	5	4	3	2	1	0
----------------	---	---	---	---	---	---	---	---

4 Gb total

Base Addressing in MIPS

There is only one way to refer to what address to load/store in MIPS: base + offset.

$-32768 < \text{offset} < 32767$

Byte Load and Store

MIPS registers are 32 bits (4 bytes). Loading a byte into a register either clears the top three bytes or sign-extends them.

The Endian Question

MIPS can also load and store 4-byte words and 2-byte halfwords.

The *endian* question: when you read a word, in what order do the bytes appear?

Little Endian: Intel, DEC, et al.

Big Endian: Motorola, IBM, Sun, et al.

MIPS can do either

SPIM adopts its host's convention

Big Endian

Little Endian

Testing Endianness

```
.data                # Directive: ''this is data''  
myword:  
  .word 0            # Define a word of data (=0)  
  
.text               # Directive: ''this is program''  
main:  
  la $t1, myword    # pseudoinstruction: load address  
  li $t0, 0x11  
  sb $t0, 0($t1)    # Store 0x11 at byte 0  
  
  li $t0, 0x22  
  sb $t0, 1($t1)    # Store 0x22 at byte 1  
  
  li $t0, 0x33  
  sb $t0, 2($t1)    # Store 0x33 at byte 2  
  
  li $t0, 0x44  
  sb $t0, 3($t1)    # Store 0x44 at byte 3  
  
  lw $t2, 0($t1)    # 0x11223344 or 0x44332211?  
  
  j $ra
```

Alignment

Word and
half-word loads
and stores must
be *aligned*:

words must start
at a multiple of
4 bytes;

halfwords on a
multiple of 2.

Byte load/store
has no such
constraint.

```
lw $t0, 4($0) # OK
lw $t0, 5($0) # BAD: 5 mod 4 = 1
lw $t0, 8($0) # OK
lw $t0, 12($0) # OK

lh $t0, 2($0) # OK
lh $t0, 3($0) # BAD: 3 mod 2 = 1
lh $t0, 4($0) # OK
```

Jump and Branch Instructions

Jump and Branch Instructions

j	Jump
jal	Jump and link
jr	Jump to register
jalr	Jump and link register
beq	Branch on equal
bne	Branch on not equal
blez	Branch on less than or equal to zero
bgtz	Branch on greater than zero
bltz	Branch on less than zero
bgez	Branch on greater than or equal to zero
bltzal	Branch on less than zero and link
bgezal	Branch on greter than or equal to zero and link

Jumps

The simplest form,

```
j mylabel  
# ...  
mylabel:  
# ...
```

sends control to the instruction at *mylabel*. Instruction holds a 26-bit constant multiplied by four; top four bits come from current PC. Uncommon.

Jump to register sends control to a 32-bit absolute address in a register:

```
jr $t3
```

Instructions must be four-byte aligned;
the contents of the register must be a multiple of 4.

Jump and Link

Jump and link stores a return address in `$ra` for implementing subroutines:

```
jal mysub  
# Control resumes here after the jr  
# ...
```

mysub:

```
# ...  
jr $ra # Jump back to caller
```

jalr is similar; target address supplied in a register.

Branches

Used for conditionals or loops. E.g., “send control to *myloop* if the contents of *\$t0* is not equal to the contents of *\$t1*.”

myloop:

...

bne *\$t0*, *\$t1*, *myloop*

...

beq is similar “branch if equal”

A “jump” supplies an absolute address; a “branch” supplies an offset to the program counter.

On the MIPS, a 16-bit signed offset is multiplied by four and added to the address of the next instruction.

Branches

Another family of branches tests a single register:

```
bgez $t0, myelse # Branch if $t0 positive  
# ...
```

```
myelse:
```

```
# ...
```

Others in this family:

blez Branch on less than or equal to zero

bgtz Branch on greater than zero

bltz Branch on less than zero

bltzal Branch on less than zero and link

bgez Branch on greater than or equal to zero

bgezal Branch on greter than or equal to zero and link

“and link” variants also (always) put the address of the next instruction into \$ra, just like **jal**.

Other Instructions

syscall causes a system call exception, which the OS catches, interprets, and usually returns from.

SPIM provides simple services: printing and reading integers, strings, and floating-point numbers, sbrk() (memory request), and exit().

```
# prints "the answer = 5"
```

```
.data
```

```
str:
```

```
.asciiz "the answer = "
```

```
.text
```

```
li $v0, 4    # system call code for print_str
```

```
la $a0, str  # address of string to print
```

```
syscall      # print the string
```

```
li $v0, 1    # system call code for print_int
```

```
li $a0, 5    # integer to print
```

```
syscall      # print it
```

Other Instructions

Exception Instructions

tge tlt ...	Conditional traps
break	Breakpoint trap, for debugging
eret	Return from exception

Multiprocessor Instructions

ll sc	Load linked/store conditional for atomic operations
sync	Read/Write fence: wait for all memory loads/stores

Coprocessor 0 Instructions (System Mgmt)

lwr lwl ...	Cache control
tlbr tblwi ...	TLB control (virtual memory)
...	Many others (data movement, branches)

Floating-point Coprocessor Instructions

add.d sub.d ...	Arithmetic and other functions
lwc1 swc1 ...	Load/store to (32) floating-point registers
bctlt ...	Conditional branches

Instruction Encoding

Register-type: **add**, **sub**, **xor**, ...

Immediate-type: **addi**, **subi**, **beq**, ...

Jump-type: **j**, **jal** ...

Register-type Encoding Example

op:6	rs:5	rt:5	rd:5	shamt:5	funct:6
------	------	------	------	---------	---------

add \$t0, \$s1, \$s2

add encoding from the MIPS instruction set reference:

SPECIAL 000000	rs	rt	rd	0 00000	ADD 100000
-------------------	----	----	----	------------	---------------

Since \$t0 is register 8; \$s1 is 17; and \$s2 is 18,

000000	10001	10010	01000	00000	100000
--------	-------	-------	-------	-------	--------

Register-type Shift Instructions

op:6	rs:5	rt:5	rd:5	shamt:5	funct:6
------	------	------	------	---------	---------

sra \$t0, \$s1, 5

sra encoding from the MIPS instruction set reference:

SPECIAL 000000	0 00000	rt	rd	sa	SRA 000011
-------------------	------------	----	----	----	---------------

Since \$t0 is register 8 and \$s1 is 17,

000000	00000	10010	01000	00101	000011
--------	-------	-------	-------	-------	--------

Immediate-type Encoding Example

op:6	rs:5	rt:5	imm:16
------	------	------	--------

addiu \$t0, \$s1, -42

addiu encoding from the MIPS instruction set reference:

ADDIU 001001	rs	rt	immediate
-----------------	----	----	-----------

Since \$t0 is register 8 and \$s1 is 17,

001001	10001	01000	1111 1111 1101 0110
--------	-------	-------	---------------------

Jump-Type Encoding Example

jal 0x5014

jal encoding from the MIPS instruction set reference:

Instruction index is a word address

Assembler Pseudoinstructions

Set if greater than	sgt d, s, t	\rightarrow slt d, t, s

Expressions

Initial expression:

$$x + y + z * (w + 3)$$

Reordered to minimize intermediate results; fully parenthesized to make order of operation clear.

$$(((w + 3) * z) + y) + x$$

```
addiu $t0, $a0, 3      # w: $a0
mul   $t0, $t0, $a3   # x: $a1
addu  $t0, $t0, $a2   # y: $a2
addu  $t0, $t0, $a1   # z: $a3
```

Consider an alternative:

$$(x + y) + ((w + 3) * z)$$

```
addu  $t0, $a1, $a2
addiu $t1, $a0, 3      # Need a second temporary
mul   $t1, $t1, $a3
addu  $t0, $t0, $t1
```

Conditionals

```
if ((x + y) < 3)
    x = x + 5;
else
    y = y + 4;
```

```
    addu $t0, $a0, $a1 # x + y
    slti $t0, $t0, 3   # (x+y)<3
    beq  $t0, $0, ELSE
    addiu $a0, $a0, 5   # x += 5
    b    DONE
ELSE:
    addiu $a1, $a1, 4   # y += 4
DONE:
```

Do-While Loops

Post-test loop: body always executes once

```
a = 0;
b = 0;
do {
    a = a + b;
    b = b + 1;
} while (b != 10);
```

```
move $a0, $0 # a = 0
move $a1, $0 # b = 0
li $t0, 10 # load constant
TOP:
addu $a0, $a0, $a1 # a = a + b
addiu $a1, $a1, 1
# b = b + 1
bne $a1, $t0, TOP # b != 10?
```

While Loops

Pre-test loop: body may never execute

```
a = 0;
b = 0;
while (b != 10) {
    a = a + b;
    b = b + 1;
}
```

```
move $a0, $0 # a = 0
move $a1, $0 # b = 0
li $t0, 10
b TEST # test first
BODY:
addu $a0, $a0, $a1 # a = a + b
addiu $a1, $a1, 1 # b = b + 1
TEST:
bne $a1, $t0, BODY # b != 10?
```

For Loops

“Syntactic sugar” for a while loop

```
for (a = b = 0 ; b != 10 ; b++)  
    a += b;
```

is equivalent to

```
a = b = 0;  
while (b != 10) {  
    a = a + b;  
    b = b + 1;  
}
```

```
move $a1, $0 # b = 0  
move $a0, $a1 # a = b  
li $t0, 10  
b TEST # test first  
BODY:  
    addu $a0, $a0, $a1 # a = a + b  
    addiu $a1, $a1, 1 # b = b + 1  
TEST:  
    bne $a1, $t0, BODY # b != 10?
```

Arrays

```
int a[5];

void main() {
    a[4] = a[3] = a[2] =
        a[1] = a[0] = 3;
    a[1] = a[2] * 4;

Subroutines

a.k.a. procedures, functions, methods, et al.

Code that can run by itself, then *resume whatever invoked it*.

Exist for three reasons:

- ▶ Code reuse
Recurring computations aside from loops
Function libraries
- ▶ Isolation/Abstraction
Think Vegas:
What happens in a function stays in the function.
- ▶ Enabling Recursion
Fundamental to divide-and-conquer algorithms

Calling Conventions

```
# Call mysub: args in $a0,...,$a3
jal mysub
# Control returns here
# Return value in $v0 & $v1
# $s0,...,$s7, $gp, $sp, $fp, $ra unchanged
# $a0,...,$a3, $t0,...,$t9 possibly clobbered
```

```
mysub: # Entry point: $ra holds return address
      # First four args in $a0, $a1, .., $a3
```

```
      # ... body of the subroutine ...
```

```
      # $v0, and possibly $v1, hold the result
      # $s0,...,$s7 restored to value on entry
      # $gp, $sp, $fp, and $ra also restored
```

```
jr $ra      # Return to the caller
```

The Stack

Towers of Hanoi

```
void move(int src, int tmp,
          int dst, int n)
{
    if (n) {
        move(src, dst, tmp, n-1);
        printf("%d->%d\n", src, dst);
        move(tmp, src, dst, n-1);
    }
}
```

hmove:

```
addiu $sp, $sp, -24  
beq    $a3, $0, L1  
sw    $ra, 0($sp)  
sw    $s0, 4($sp)  
sw    $s1, 8($sp)  
sw    $s2, 12($sp)  
sw    $s3, 16($sp)
```

\$a0	\$a1	\$a2	\$a3
src	tmp	dst	n

Allocate 24 stack bytes:
multiple of 8 for alignment

Check whether `n == 0`

Save `$ra, $s0, ..., $s3` on
the stack

hmove:

```
addiu $sp, $sp, -24  
beq   $a3, $0, L1  
sw    $ra, 0($sp)  
sw    $s0, 4($sp)  
sw    $s1, 8($sp)  
sw    $s2, 12($sp)  
sw    $s3, 16($sp)  
  
move  $s0, $a0  
move  $s1, $a1  
move  $s2, $a2  
addiu $s3, $a3, -1
```

Save src in \$s0

Save tmp in \$s1

Save dst in \$s2

Save n - 1 in \$s3

hmove:

```
addiu $sp, $sp, -24
beq   $a3, $0, L1

    lw    $ra, 4($sp) # return address  
    mul   $v0, $a0, $v0 # Compute n * fact(n-1)  
    addiu $sp, $sp, 8 # Pop 2 words from stack  
    jr    $ra # return
```

Memory Layout

Differences in Other ISAs

More or fewer general-purpose registers (E.g., Itanium: 128; 6502: 3)

Arithmetic instructions affect condition codes (e.g., zero, carry); conditional branches test these flags

Registers that are more specialized (E.g., x86)

More addressing modes (E.g., x86: 6; VAX: 20)

Arithmetic instructions that also access memory (E.g., x86; VAX)

Arithmetic instructions on other data types (E.g., bytes and halfwords)

Variable-length instructions (E.g., x86; ARM)

Predicated instructions (E.g., ARM, VLIW)

Single instructions that do much more (E.g., x86 string move, procedure entry/exit)
