```
al·go·rithm

a procedure for solving a mathematical problem (as of finding the greatest common divisor) in a finite number of steps that frequently involves repetition of an operation; broadly : a step-by-step procedure for solving a problem or accomplishing some end especially by a computer

Merriam-Webster
The Stored-Program Computer

“Since the device is primarily a computer, it will have to perform the elementary operations of arithmetics most frequently. [...] It is therefore reasonable that it should contain *specialized organs for just these operations*.

“If the device is to be [...] as nearly as possible all purpose, then a distinction must be made between the specific instructions given for and defining a particular problem, and the general control organs which see to it that these instructions [...] are carried out. The former must be *stored in some way* [...] the latter are represented by definite operating parts of the device.

“Any device which is to carry out long and complicated sequences of operations (specifically of calculations) *must have a considerable memory*. 
Instruction Set Architecture (ISA)

ISA: The interface or contact between the hardware and the software

Rules about how to code and interpret machine instructions:

- Execution model (program counter)
- Operations (instructions)
- Data formats (sizes, addressing modes)
- Processor state (registers)
- Input and Output (memory, etc.)
Architecture vs. Microarchitecture

Architecture: The interface the hardware presents to the software

Microarchitecture: The detailed implementation of the architecture
Microprocessor without Interlocked Pipeline Stages

RISC vs. CISC Architectures

MIPS is a Reduced Instruction Set Computer (RISC). Others include ARM, PowerPC, SPARC, HP-PA, and Alpha.

A Complex Instruction Set Computer (CISC) is one alternative. Intel’s x86 is the most prominent example; also Motorola 68000 and DEC VAX.

RISC’s underlying principles, due to Hennessy and Patterson:

- Simplicity favors regularity
- Make the common case fast
- Smaller is faster
- Good design demands good compromises
The GCD Algorithm

Euclid, *Elements*, 300 BC.

The greatest common divisor of two numbers does not change if the smaller is subtracted from the larger.

1. Call the two numbers \( a \) and \( b \)
2. If \( a \) and \( b \) are equal, stop: \( a \) is the greatest common divisor
3. Subtract the smaller from the larger
4. Repeat steps 2–4
The GCD Algorithm

Let’s be a little more explicit:

1. Call the two numbers $a$ and $b$
2. If $a$ equals $b$, go to step 8
3. If $a$ is less than $b$, go to step 6
4. Subtract $b$ from $a$  \[ a > b \text{ here} \]
5. Go to step 2
6. Subtract $a$ from $b$  \[ a < b \text{ here} \]
7. Go to step 2
8. Declare $a$ the greatest common divisor
9. Go back to doing whatever you were doing before
Euclid’s Algorithm in MIPS Assembly

gcd:

```
beq $a0, $a1, .L2  # if a = b, go to exit
sgt $v0, $a1, $a0  # Is b > a?
bne $v0, $zero, .L1 # Yes, goto .L1

subu $a0, $a0, $a1  # Subtract b from a (b < a)
      b      gcd  # and repeat

.L1:

subu $a1, $a1, $a0  # Subtract a from b (a < b)
      b      gcd  # and repeat

.L2:

move $v0, $a0  # return a
      j      $ra  # Return to caller
```

Computational Instructions

Arithmetic, logical, and other computations. Example:

```
add $t0, $t1, $t3
```

“Add the contents of registers $t1 and $t3; store the result in $t0”

Register form:

```
operation RD, RS, RT
```

“Perform operation on the contents of registers RS and RT; store the result in RD”

Passes control to the next instruction in memory after running.
Arithmetic Instruction Example

<table>
<thead>
<tr>
<th></th>
<th>a</th>
<th>b</th>
<th>c</th>
<th>f</th>
<th>g</th>
<th>h</th>
<th>i</th>
<th>j</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>$s0</td>
<td>$s1</td>
<td>$s2</td>
<td>$s3</td>
<td>$s4</td>
<td>$s5</td>
<td>$s6</td>
<td>$s7</td>
</tr>
</tbody>
</table>

\[
a = b - c;\]
\[
f = (g + h) - (i + j);\]

```
subu $s0, $s1, $s2
addu $t0, $s4, $s5
addu $t1, $s6, $s7
subu $s3, $t0, $t1
```

“Signed” addition/subtraction (\texttt{add/sub}) throw an exception on a two’s-complement overflow; “Unsigned” variants (\texttt{addu/subu}) do not. Resulting bit patterns otherwise identical.
Bitwise Logical Operator Example

```
li $t0, 0xFF00FF00  # "Load immediate"
li $t1, 0xF0F0F0F0  # "Load immediate"

nor $t2, $t0, $t1  # Puts 0x000F000F in $t2

li $v0, 1          # print_int
move $a0, $t2      # print contents of $t2
syscall
```
Immediate Computational Instructions

Example:

```
addiu $t0, $t1, 42
```

“Add the contents of register $t1 and 42; store the result in register $t0”

In general,

```
operation R_D, R_S, I
```

“Perform operation on the contents of register $R_S$ and the signed 16-bit immediate $I$; store the result in $R_D$”

Thus, $I$ can range from $-32768$ to $32767$. 
32-Bit Constants and lui

It is easy to load a register with a constant from –32768 to 32767, e.g.,

$$\text{ori } t0, 0, 42$$

Larger numbers use “load upper immediate,” which fills a register with a 16-bit immediate value followed by 16 zeros; an OR handily fills in the rest. E.g., Load $t0$ with 0xC0DEFACE:

$$\text{lui } t0, 0\times\text{CODE}$$  
$$\text{ori } t0, t0, 0x\text{FACE}$$

The assembler automatically expands the li pseudo-instruction into such an instruction sequence

$$\text{li } t1, 0\times\text{CAFE0B0E} \rightarrow \text{lui } t1, 0\times\text{CAFE}$$  
$$\text{ori } t1, t1, 0\times\text{BOE}$$
Multiplication and Division

Multiplication gives 64-bit result in two 32-bit registers: HI and LO. Division: LO has quotient; HI has remainder.

```c
int multdiv(
    int a, // $a0
    int b, // $a1
    unsigned c, // $a2
    unsigned d) // $a3
{
    a = a * b + c;
    c = c * d + a;

    a = a / c;
    b = b % a;
    c = c / d;
    d = d % c;

    return a + b + c + d;
}
```

```
multdiv:
    mult $a0,$a1 # a * b
    mflo $t0
    addu $a0,$t0,$a2 # a = a*b + c
    mult $a2,$a3 # c * d
    mflo $t1
    addu $a2,$t1,$a0 # c = c*d + a
    divu $a0,$a2 # a / c
    mflo $a0 # a = a/c
    divu $0,$a1,$a0 # b % a
    mfhi $a1 # b = b%a
    divu $a2,$a3 # c / d
    mflo $a2 # c = c/d
    addu $t2,$a0,$a1 # a + b
    addu $t2,$t2,$a2 # (a+b) + c
    divu $a3,$a2 # d % c
    mfhi $a3 # d = d%c
    addu $v0,$t2,$a3 # ((a+b)+c) + d
    j $ra
```
Shift Left

Shifting left amounts to multiplying by a power of two. Zeros are added to the least significant bits. The constant form explicitly specifies the number of bits to shift:

```
sl
$a0, $a0, 1
```

The variable form takes the number of bits to shift from a register (mod 32):

```
sllv $a1, $a0, $t0
```
The logical form of right shift adds 0’s to the MSB.

```
srl $a0, $a0, 1
```

31 30 \[\cdots\] 2 1 0

0
Shift Right Arithmetic

The “arithmetic” form of right shift sign-extends the word by copying the MSB.

{sra} $a0, $a0, 2
Set on Less Than

\[ \text{slt } \$t0, \$t1, \$t2 \]

Set \$t0 to 1 if the contents of \$t1 \(<\) \$t2; 0 otherwise. \$t1 and \$t2 are treated as 32-bit signed two's complement numbers.

```c
int compare(int a, // $a0
    int b, // $a1
    unsigned c, // $a2
    unsigned d) // $a3
{
    int r = 0; // $v0
    if (a < b) r += 42;
    if (c < d) r += 99;
    return r;
}
```

```assembly
    compare:
        move $v0, $zero
        slt $t0, $a0, $a1
        beq $t0, $zero, .L1
        addi $v0, $v0, 42
    .L1:
        sltu $t0, $a2, $a3
        beq $t0, $zero, .L2
        addi $v0, $v0, 99
    .L2:
        j $ra
```

</tbody>
</table>
Memory on the MIPS

Memory is byte-addressed. Each byte consists of eight bits:

\[
\begin{array}{cccccccc}
7 & 6 & 5 & 4 & 3 & 2 & 1 & 0 \\
\end{array}
\]

Bytes have non-negative integer addresses. Byte addresses on the 32-bit MIPS processor are 32 bits; 64-bit processors usually have 64-bit addresses.

\[
\begin{array}{cccccccc}
0: & 7 & 6 & 5 & 4 & 3 & 2 & 1 & 0 \\
1: & 7 & 6 & 5 & 4 & 3 & 2 & 1 & 0 \\
2: & 7 & 6 & 5 & 4 & 3 & 2 & 1 & 0 \\
\vdots \\
2^{32} - 1: & 7 & 6 & 5 & 4 & 3 & 2 & 1 & 0 \\
\end{array}
\]

4 Gb total
There is only one way to refer to what address to load/store in MIPS: base + offset.

```assembly
lb $t0, 34($t1)
```

$t1: 00000008 (base register)

$42: EF

$t0: FFFFFFFFEF

$−32768 < offset < 32767
MIPS registers are 32 bits (4 bytes). Loading a byte into a register either clears the top three bytes or sign-extends them.

```
42: F0

lbu $t0, 42($0)
$t0: 000000F0
```

```
42: F0

lb $t0, 42($0)
$t0: FFFFFFFF0
```
MIPS can also load and store 4-byte words and 2-byte halfwords.

The *endian* question: when you read a word, in what order do the bytes appear?

Little Endian: Intel, DEC, et al.

Big Endian: Motorola, IBM, Sun, et al.

MIPS can do either

SPIM adopts its host’s convention
Testing Endianness

.data  # Directive: ‘‘this is data’’
myword:
  .word 0  # Define a word of data (=0)
.text  # Directive: ‘‘this is program’’
main:
  la $t1, myword  # pseudoinstruction: load address
  li $t0, 0x11
  sb $t0, 0($t1)  # Store 0x11 at byte 0
  li $t0, 0x22
  sb $t0, 1($t1)  # Store 0x22 at byte 1
  li $t0, 0x33
  sb $t0, 2($t1)  # Store 0x33 at byte 2
  li $t0, 0x44
  sb $t0, 3($t1)  # Store 0x44 at byte 3
  lw $t2, 0($t1)  # 0x11223344 or 0x44332211?
j $ra
Alignment

Word and half-word loads and stores must be *aligned*: words must start at a multiple of 4 bytes; halfwords on a multiple of 2.

Byte load/store has no such constraint.

```bash
lw $t0, 4($0) # OK
lw $t0, 5($0) # BAD: 5 mod 4 = 1
lw $t0, 8($0) # OK
lw $t0, 12($0) # OK

lh $t0, 2($0) # OK
lh $t0, 3($0) # BAD: 3 mod 2 = 1
lh $t0, 4($0) # OK
```
### Jump and Branch Instructions

</tr>
</tbody>
</table>
Jumps

The simplest form,

```
j  mylabel
  # ...
mylabel:
  # ...
```

sends control to the instruction at `mylabel`. Instruction holds a 26-bit constant multiplied by four; top four bits come from current PC. Uncommon.

Jump to register sends control to a 32-bit absolute address in a register:

```
jr  $t3
```

Instructions must be four-byte aligned; the contents of the register must be a multiple of 4.
Jump and Link

Jump and link stores a return address in $ra for implementing subroutines:

```assembly
jal mysub
#  Control resumes here after the jr
#  ...
```

```assembly
mysub:
#  ...
    jr $ra  # Jump back to caller
```

`jalr` is similar; target address supplied in a register.
Branches

Used for conditionals or loops. E.g., “send control to *myloop* if the contents of $t0$ is not equal to the contents of $t1$.”

myloop:
    # ...

    bne $t0, $t1, myloop
    # ...

*beq* is similar “branch if equal”

A “jump” supplies an absolute address; a “branch” supplies an offset to the program counter.

On the MIPS, a 16-bit signed offset is multiplied by four and added to the address of the next instruction.
Branches

Another family of branches tests a single register:

    bgez $t0, myelse  # Branch if $t0 positive
    # ...

    myelse:
    # ...

Others in this family:

    blez       Branch on less than or equal to zero
    bgtz       Branch on greater than zero
    bltz       Branch on less than zero
    bltzal     Branch on less than zero and link
    bgez       Branch on greater than or equal to zero
    bgezal     Branch on greater than or equal to zero and link

“and link” variants also (always) put the address of the next instruction into $ra, just like jal.
Other Instructions

**syscall** causes a system call exception, which the OS catches, interprets, and usually returns from.

SPIM provides simple services: printing and reading integers, strings, and floating-point numbers, sbrk() (memory request), and exit().

```assembly
.data
str:  
    .asciiz "the answer = 
.text
li $v0, 4  # system call code for print_str
la $a0, str # address of string to print
syscall    # print the string

li $v0, 1  # system call code for print_int
li $a0, 5  # integer to print
syscall    # print it
```
### Other Instructions

#### Exception Instructions

<table>
<thead>
<tr>
<th>Instruction</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>tge tlt ...</td>
<td>Conditional traps</td>
</tr>
<tr>
<td>break</td>
<td>Breakpoint trap, for debugging</td>
</tr>
<tr>
<td>eret</td>
<td>Return from exception</td>
</tr>
</tbody>
</table>

#### Multiprocessor Instructions

<table>
<thead>
<tr>
<th>Instruction</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ll sc</td>
<td>Load linked/store conditional for atomic operations</td>
</tr>
<tr>
<td>sync</td>
<td>Read/Write fence: wait for all memory loads/stores</td>
</tr>
</tbody>
</table>

#### Coprocessor 0 Instructions (System Mgmt)

<table>
<thead>
<tr>
<th>Instruction</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>lwr lwl ...</td>
<td>Cache control</td>
</tr>
<tr>
<td>tlbr tblwi ...</td>
<td>TLB control (virtual memory)</td>
</tr>
<tr>
<td>...</td>
<td>Many others (data movement, branches)</td>
</tr>
</tbody>
</table>

#### Floating-point Coprocessor Instructions

<table>
<thead>
<tr>
<th>Instruction</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>add.d sub.d ...</td>
<td>Arithmetic and other functions</td>
</tr>
<tr>
<td>lwcl swcl ...</td>
<td>Load/store to (32) floating-point registers</td>
</tr>
<tr>
<td>bctlt ...</td>
<td>Conditional branches</td>
</tr>
</tbody>
</table>
**Instruction Encoding**

Register-type: `add, sub, xor, ...`

<table>
<thead>
<tr>
<th>op:6</th>
<th>rs:5</th>
<th>rt:5</th>
<th>rd:5</th>
<th>shamt:5</th>
<th>funct:6</th>
</tr>
</thead>
</table>

Immediate-type: `addi, ori, beq, ...`

<table>
<thead>
<tr>
<th>op:6</th>
<th>rs:5</th>
<th>rt:5</th>
<th>imm:16</th>
</tr>
</thead>
</table>

Jump-type: `j, jal ...`

<table>
<thead>
<tr>
<th>op:6</th>
<th>addr:26</th>
</tr>
</thead>
</table>
Register-type Encoding Example

<table>
<thead>
<tr>
<th>op:6</th>
<th>rs:5</th>
<th>rt:5</th>
<th>rd:5</th>
<th>shamt:5</th>
<th>funct:6</th>
</tr>
</thead>
</table>

```
add $t0, $s1, $s2
```

**add** encoding from the MIPS instruction set reference:

<table>
<thead>
<tr>
<th>SPECIAL</th>
<th>rs</th>
<th>rt</th>
<th>rd</th>
<th>000000</th>
<th>ADD</th>
</tr>
</thead>
<tbody>
<tr>
<td>000000</td>
<td>rs</td>
<td>rt</td>
<td>rd</td>
<td>000000</td>
<td>100000</td>
</tr>
</tbody>
</table>

Since $t0 is register 8; $s1 is 17; and $s2 is 18,

```
000000 10001 10010 01000 00000 100000
```
Register-type Shift Instructions

\[
\begin{array}{cccccc}
\text{op:6} & \text{rs:5} & \text{rt:5} & \text{rd:5} & \text{shamt:5} & \text{funct:6} \\
\hline
\end{array}
\]

\textbf{sra} \ $t0, $s1, 5$

\textbf{sra} encoding from the MIPS instruction set reference:

\[
\begin{array}{cccccc}
\text{SPECIAL} & 0 & 0 & \text{rt} & \text{rd} & \text{sa} & \text{SRA} \\
000000 & 00000 & 10010 & 01000 & 00101 & 000011 \\
\end{array}
\]

Since $t0$ is register 8 and $s1$ is 17,

\[
\begin{array}{ccccccccc}
000000 & 00000 & 10010 & 01000 & 00101 & 000011 \\
\end{array}
\]
Immediate-type Encoding Example

\[ \text{addiu } \$t0, \$s1, -42 \]

\text{addiu} encoding from the MIPS instruction set reference:

\[
\begin{array}{c|cccc}
\text{ADDIU} & \text{rs} & \text{rt} & \text{immediate} \\
001001 & 10001 & 01000 & 1111 1111 1101 0110 \\
\end{array}
\]

Since \$t0 is register 8 and \$s1 is 17,
# Jump-Type Encoding Example

<table>
<thead>
<tr>
<th>op:6</th>
<th>addr:26</th>
</tr>
</thead>
</table>

`jal 0x5014`

`jal` encoding from the MIPS instruction set reference:

<table>
<thead>
<tr>
<th>JAL</th>
<th>instr_index</th>
</tr>
</thead>
<tbody>
<tr>
<td>000011</td>
<td></td>
</tr>
</tbody>
</table>

Instruction index is a word address

<p>| 000011 | 00 0000 0000 0001 0100 0000 0101 |</p>
<table>

</table>
Expressions

Initial expression:

\[ x + y + z \times (w + 3) \]

Reordered to minimize intermediate results; fully parenthesized to make order of operation clear.

\[ (((w + 3) \times z) + y) + x \]

```
addiu $t0, $a0, 3  # w: $a0
mul $t0, $t0, $a3  # x: $a1
addu $t0, $t0, $a2  # y: $a2
addu $t0, $t0, $a1  # z: $a3
```

Consider an alternative:

\[ (x + y) + ((w + 3) \times z) \]

```
addu $t0, $a1, $a2
addiu $t1, $a0, 3  # Need a second temporary
mul $t1, $t1, $a3
addu $t0, $t0, $t1
```
Conditionals

if ((x + y) < 3)
  x = x + 5;
else
  y = y + 4;

addu $t0, $a0, $a1  # x + y
slti $t0, $t0, 3    # (x+y)<3
beq $t0, $0, ELSE
addiu $a0, $a0, 5  # x  +=  5
b DONE

ELSE:
  addiu $a1, $a1, 4  # y  +=  4
DONE:
Do-While Loops

Post-test loop: body always executes once

```plaintext
a = 0;
b = 0;
do {
    a = a + b;
b = b + 1;
} while (b != 10);
```

```assembly
move $a0, $0 # a = 0
move $a1, $0 # b = 0
li $t0, 10 # load constant

TOP:
addu $a0, $a0, $a1 # a = a + b
addiu $a1, $a1, 1 # b = b + 1
bne $a1, $t0, TOP # b != 10?
```

51 / 67
While Loops

Pre-test loop: body may never execute

```c
int a = 0;
int b = 0;
while (b != 10) {
    a = a + b;
    b = b + 1;
}
```

```assembly
move $a0, $0  # a = 0
move $a1, $0  # b = 0
li $t0, 10    
TEST  # test first

BODY:
addu $a0, $a0, $a1  # a = a + b
addiu $a1, $a1, 1  # b = b + 1

TEST:
bne $a1, $t0, BODY  # b != 10?
```
For Loops

“Syntactic sugar” for a while loop

```plaintext
for (a = b = 0 ; b != 10 ; b++)
    a += b;
```

is equivalent to

```plaintext
a = b = 0;
while (b != 10) {
    a = a + b;
    b = b + 1;
}
```

```plaintext
move $a1, $0    # b = 0
move $a0, $a1  # a = b
li $t0, 10
b TEST         # test first

BODY:
addu $a0, $a0, $a1 # a = a + b
addiu $a1, $a1, 1 # b = b + 1

TEST:
bne $a1, $t0, BODY # b != 10?
```
Arrays

```c

Subroutines

a.k.a. procedures, functions, methods, et al.

Code that can run by itself, then *resume whatever invoked it*.

Exist for three reasons:

- **Code reuse**
  Recurring computations aside from loops
  Function libraries

- **Isolation/Abstraction**
  Think Vegas:
  What happens in a function stays in the function.

- **Enabling Recursion**
  Fundamental to divide-and-conquer algorithms
Calling Conventions

# Call mysub: args in $a0,...,$a3
jal mysub
# Control returns here
# Return value in $v0 & $v1
# $s0,...,$s7, $gp, $sp, $fp, $ra unchanged
# $a0,...,$a3, $t0,...,$t9 possibly clobbered

mysub:  # Entry point: $ra holds return address
    # First four args in $a0, $a1, .., $a3

    # ... body of the subroutine ...

    # $v0, and possibly $v1, hold the result
    # $s0,...,$s7 restored to value on entry
    # $gp, $sp, $fp, and $ra also restored
jr $ra     # Return to the caller

Factorial Example

```c
int fact(int n) {
    if (n < 1) return 1;
    else return (n * fact(n - 1));
}
```

fact:

```assembly
addiu $sp, $sp, -8      # allocate 2 words on stack
sw $ra, 4($sp)          # save return address
sw $a0, 0($sp)          # and n
slti $t0, $a0, 1        # n < 1?
beq $t0, $0, ELSE
li $v0, 1               # Yes, return 1
addiu $sp, $sp, 8       # Pop 2 words from stack
jr $ra                   # return
ELSE:

addiu $a0, $a0, -1      # No: compute n-1
jal fact                # recurse (result in $v0)
lw $a0, 0($sp)          # Restore n and
lw $ra, 4($sp)          # return address
mul $v0, $a0, $v0       # Compute n * fact(n-1)
addiu $sp, $sp, 8       # Pop 2 words from stack
jr $ra                   # return
```

Differences in Other ISAs

More or fewer general-purpose registers (E.g., Itanium: 128; 6502: 3)

Arithmetic instructions affect condition codes (e.g., zero, carry); conditional branches test these flags

 Registers that are more specialized (E.g., x86)

More addressing modes (E.g., x86: 6; VAX: 20)

Arithmetic instructions that also access memory (E.g., x86; VAX)

Arithmetic instructions on other data types (E.g., bytes and halfwords)

Variable-length instructions (E.g., x86; ARM)

Predicated instructions (E.g., ARM, VLIW)

Single instructions that do much more (E.g., x86 string move, procedure entry/exit)
