

Dialect Translation: Integrating Bayesian Co-segmentation Models with Pivot-based SMT

◆ ◆ ◆ ◆ ◆
M. Paul, A. Finch, P. R. Dixon, and E. Sumita

Presented by Wael Salloum
Course: Bayesian Analysis for NLP
Instructor: Shay Cohen, Ph.D.
Columbia University
May 6th 2013

Problem Definition

- ✦ Task: Translate Dialects into Foreign (Target) Languages.
 - ✦ Source Japanese dialects: (Kumamoto, Kyoto, Okinawa, Osaka)
 - ✦ Target Languages:
 - ✦ Indo-European languages (English, German, Russian, Hindi)
 - ✦ Asian languages (Chinese, Korean)
- ✦ Problems:
 - ✦ Dialects are resource-poor languages:
 - ✦ Limited parallel data to train Statistical Machine Translation (SMT)
 - ✦ Limited NLP tools (e.g., word segmentation)

Approaches

- ✦ Direct Translation
- ✦ Pivot-based Translation:
 - ✦ SMT-based Pivot Translation: Dialect-to-Standard SMT followed by Standard-to-Target SMT
 - ✦ BCS-based Pivot Translation: Dialect-to-Standard **Transduction** followed by Standard-to-Target SMT

Statistical Machine Translation

✦ A maximization problem:

$$\operatorname{argmax}_{trg} p(src|trg) * p(trg)$$

Dialect-to-Standard Transduction

- ✦ Bayesian co-segmentation (BCS) model
- ✦ Joint-source channel model (n -gram transliteration model)

Dialect-to-Standard Transduction

- ✦ **Transliteration:** character-to-character mapping to transfer *Dialect* sentences to *Standard* word segments.
- ✦ The paper uses a **Generative Bayesian Model:**
 - ✦ Avoids *over-fitting*.
 - ✦ Constructs *compact* models that have only a small number of *well-chosen* parameters.
 - ✦ Is based on *joint source channel model*.
 - ✦ Is *symmetric* w.r.t. source and target languages.

Joint-Source Channel Model

- ✦ A Dialect sentence: $\sigma = l_1, l_2, \dots, l_L$ (l is a character)
- ✦ A Standard sentence: $\omega = s_1, s_2, \dots, s_S$ (s is a word token)
- ✦ There exists an **alignment**

$$\gamma = \langle l_1 \dots l_q, s_1 \rangle, \dots, \langle l_r \dots l_L, s_S \rangle$$

of K transliteration units.

→ The n-gram model: the transliteration probability of a transliteration pair $\langle l, s \rangle_k$ depending on its immediate n preceding transliteration pairs:

$$P(\sigma, \omega, \gamma) = \prod_{k=1}^K P(\langle l, s \rangle_k | \langle l, s \rangle_{k-n+1}^{k-1})$$

Bayesian co-segmentation (BCS)

- ✦ Two Models:
 - ✦ A model for *generating* an outcome that has already been generated at least once before
 - ✦ A model for *assigning* a probability to an outcome that has not yet been produced
- ✦ The co-segmentation process is driven by a Dirichlet process. The underlying stochastic process for the generation of a corpus of bilingual phrase pairs (s_k, t_k) :

$$\begin{aligned} G | \alpha, G_0 &\sim DP(\alpha, G_0) \\ (s_k, t_k) | G &\sim G \end{aligned}$$

Bayesian co-segmentation (BCS)

- ✦ The base measure G_0 controls the generation of novel sequence pairs: A joint spelling model to assign probabilities to them:

$$\begin{aligned} G_0((\mathbf{s}, \mathbf{t})) &= p(|\mathbf{s}|)p(\mathbf{s}||\mathbf{s}|) \times p(|\mathbf{t}|)p(\mathbf{t}||\mathbf{t}|) \\ &= \frac{\lambda_s^{|\mathbf{s}|}}{|\mathbf{s}|!} e^{-\lambda_s} v_s^{-|\mathbf{s}|} \times \frac{\lambda_t^{|\mathbf{t}|}}{|\mathbf{t}|!} e^{-\lambda_t} v_t^{-|\mathbf{t}|} \end{aligned}$$

- ✦ The generative model:

$$\begin{aligned} p((\mathbf{s}_k, \mathbf{t}_k)|(\mathbf{s}_{-k}, \mathbf{t}_{-k})) \\ = \frac{N((\mathbf{s}_k, \mathbf{t}_k)) + \alpha G_0((\mathbf{s}_k, \mathbf{t}_k))}{N + \alpha} \end{aligned}$$

Bayesian co-segmentation (BCS)

- ✦ **Sampling:** Blocked Gibbs sampler
- ✦ Extended the forward filtering / backward sampling DP algorithm to deal with bilingual segmentation.

Experiments

Approaches

- ✦ Direct Translation
- ✦ Pivot-based Translation:
 - ✦ SMT-based Pivot Translation: Dialect-to-Standard SMT followed by Standard-to-Target SMT
 - ✦ BCS-based Pivot Translation: Dialect-to-Standard **Transduction** followed by Standard-to-Target SMT

Direct Translation

Table 2: SMT-based Direct Translation Quality
BLEU (%)
