## System Overview

The VoIP telephone we're designing is built to support a minimal set of SIP, as we will focus on the necessary implementation of audio I/O, audio trans-coding, and networking.

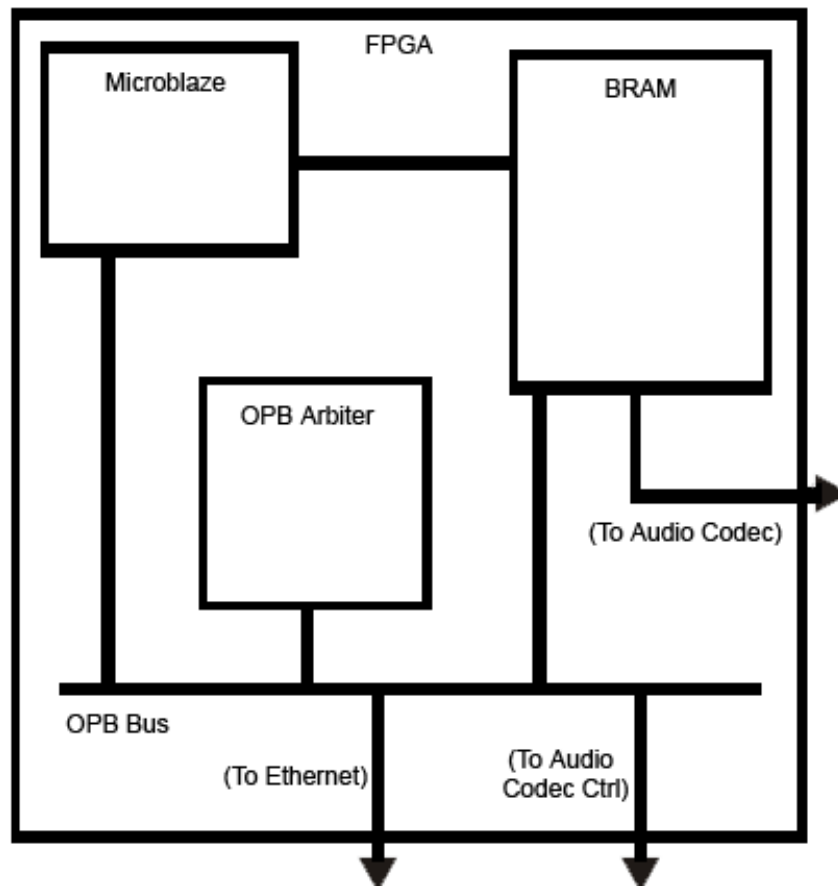

The phone works as follows:

We will take audio input from the audio codec and store this data serially and temporarily in a block of BRAM. This audio data will be converted from 16-bit linear to 8-bit ulaw via the G.711 audio codec on the microblaze. The output of the G.711 codec will be stored in parallel in another BRAM block. From there, the sample is ready to be injected into a UDP packet and sent to the ethernet controller buffer.

The components of the board that will be used are:

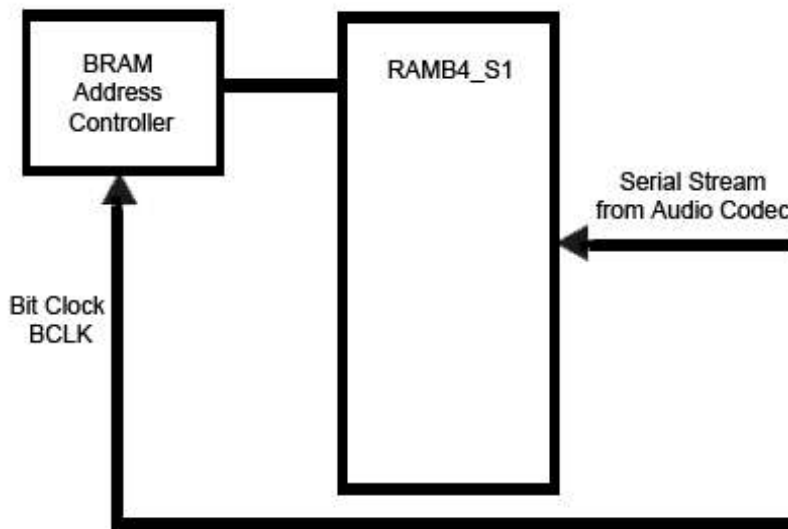

The FPGA will be used as follows:

## Audio Interface

This is the timing diagram for AK4565 Audio Codec, ignoring stereo input (taken from the Asahi Kasei datasheet, modified for our purposes). When LRCK is low, the codec samples from the right channel, but we are only interested in monophonic recording, so we will ignore the right channel and use the left as the only signal. Running the bit clock (BCLK) at 32 times the sampling frequency (LRCK) we can force the 20-bit codec to serially output 16-bits. By ignoring the stereo nature of the codec we can also operate in half duplex, reading on LRCK high and writing on LRCK low. Hopefully this will simplify timing.

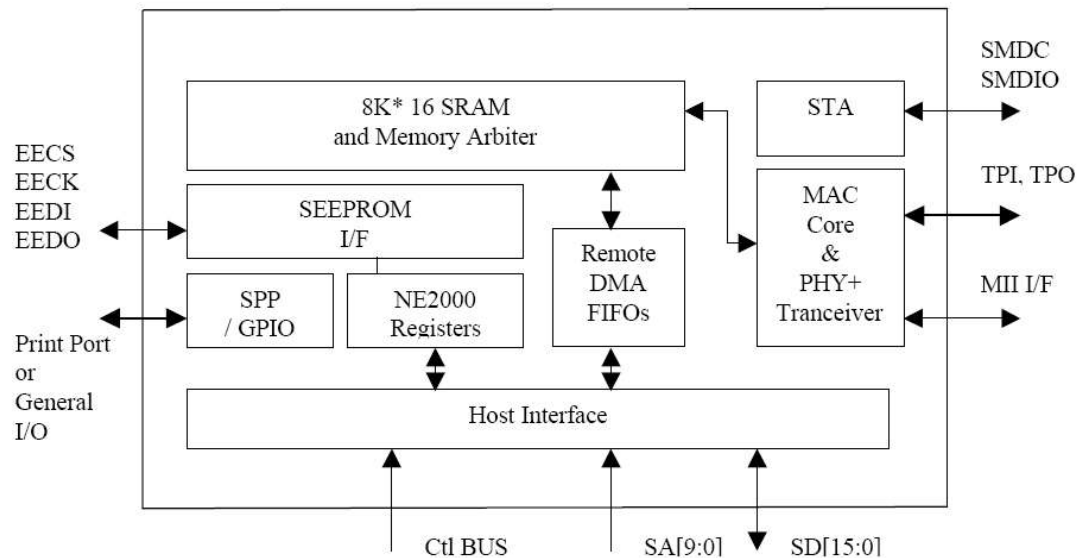

The serial bitstream from the audio codec will be stored into one block of RAMB4\_S1 implemented block RAM. This way, a counter can be synchronized with the bit clock (BCLK) of the audio codec to correctly address the incoming bits.

## G.711 Encoding

The 16-bit linear data stored in the RAMB4\_S1 block will be read by the microblaze and converted into the G.711 format (8-bit  $\mu$ -law) via code provided by Prof. Schulzrinne ([hgs@cs.columbia.edu](mailto:hgs@cs.columbia.edu)). This format is preferred for voice telephony because it lowers overall resolution, allowing for faster data transfer, and it is more sensitive to amplitude changes in lower magnitudes. The G.711 encoded audio data will be stored in parallel in a RAMB4\_S8 block and is ready to be injected into packets.

## Ethernet Controller Interface

Team JAYCam, from last year's class, was able to successfully use the ethernet controller. We plan to adopt a large deal of their code, which supports UDP transmission, and augment that code for UDP reception.

### Memory Addressing:

NE2000 registers – x00A00000 – x00A0001F

SRAM Local Memory – x00A04000 – x00A07FFF

### Ethernet Buffers

The ethernet 8k x 16 SRAM acts as a buffer for both incoming and outgoing data. The buffer can be split as desired between these two functions, and we will divide them evenly, as there is no compelling reason to hold a larger buffer in either direction.

Data is transmitted by performing a Remote DMA write. Data is received by performing a Remote DMA read.

### Timing – General

We will introduce a 100MHz clock, and the IO Pads of the FPGA support this. This higher clock speed allows for proper state change and signal transfer between the FPGA and ethernet controller.

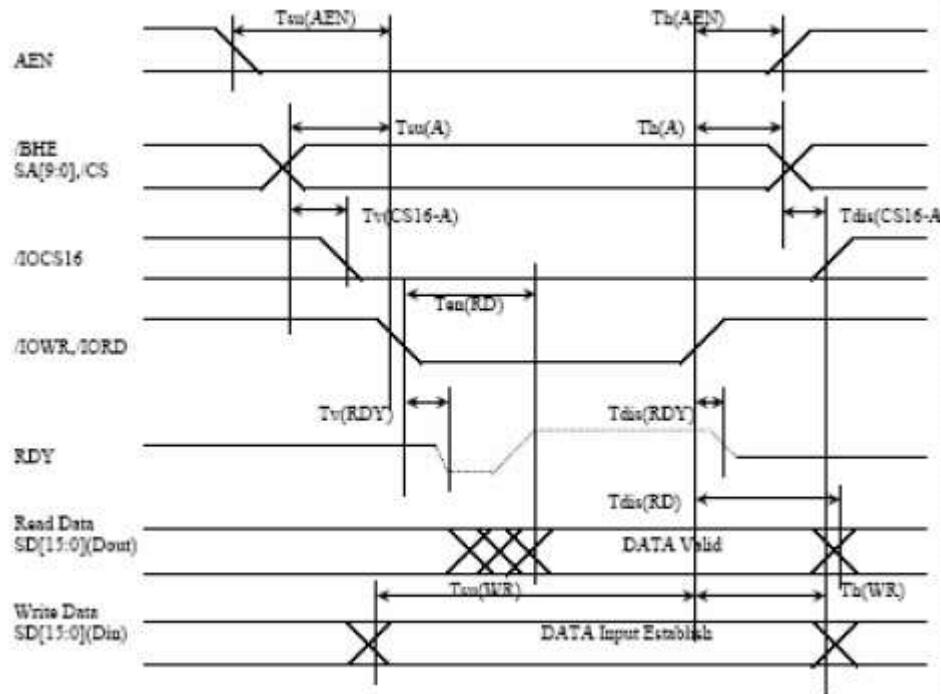

### Timing - Transmission

As noted by JAYCam, the timing diagram provided by the manufacturer is incorrect. The CS, BHE, AE, Add, and WE signals cannot be asserted at the same time, but rather require delay, with CS coming before WE, and all after an overall 5ns initial setup time. This yields a 4-step FSM: 1) All signals except WE asserted 2) WE asserted (making the address and data signals valid) 3) Wait cycle (because DMA may be too slow) 4) Data disabling

### Timing – Receiving

We anticipate timing issues with the timing diagram provided by the manufacturer. Nevertheless, we will experiment along the same lines as JAYCam did to solve these problems. The timing diagram for receiving is nearly equivalent to that of transmitting, so the fixes above may allow receiving to work, as well.

### Timing Diagram

Team JAYCam provides a complete reference on performing the ethernet initialization with the NE2000 registers for Remote DMA read, and Remote DMA write.

## Ethernet Software

Ethernet packets will be assembled by the Microblaze in software by retrieving audio data in the parallel BRAM, generating the entire UDP packet in BRAM, and sending the packet to the Ethernet transmission buffers.

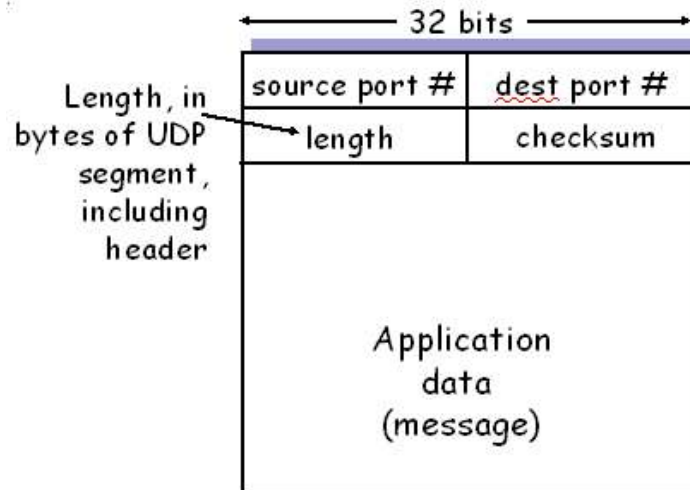

The structure of the IP packet is:

Destination Address	6 Bytes
Source Address	6 Bytes
Length / Type	2 Bytes
Data (Pad if < 46 Bytes)	46 Bytes Min.

General Transmit Packet Format

This is not the standard structure for an IP packet, but rather the structure of the packet as received by the ethernet controller, where the data is taken and formed into a standard IP packet. The checksum, etc.. are automatically handled by the controller.

The UDP packet is placed within the IP packet and has the following structure:

The application data message is specific to the protocol. The protocols we will implement are: SIP, RTP, SDP

### **SIP/SDP (Application Layer UDP Data Body)**

SIP (Session Initiation Protocol) will be used to communicate properly with standard VoIP services. To accomplish this, we also need to implement SDP and RTP. SDP (Session Description Protocol) is used upon connection to agree on a codec, as in most operation multiple CODECs are available on both the client and server end. In our case, however, we support only G711mu-law, and the SDP response will indicate this. RTP (Real-Time Protocol) is used for audio data transfer during phone calls. This is a simply implemented protocol which, minus a very small header, simply sends the next few samples in the audio stream [observation shows that in general about 20 samples per packet]. Packet sniffed data from a VoIP phone utilizing these protocols is included in Appendix A.

SIP Reference: <http://www.ietf.org/rfc/rfc2543.txt>

SIP Sequence of Events:

#1: "REGISTER" (see attached packet #1)  
Sent from phone to gateway

Note that the username and password for the VoIP account are included in the original REGISTER command. Normally, the phone will send a REGISTER without the password and wait for a 401 Unauthorized in return. Our phone will skip this step and send originally with the password. The password has been omitted from the packet sniffed data in the appendix.

#2: "200 OK" (attached packet #2)  
Sent from gateway to phone to acknowledge proper registration

To place a call:

#3: "INVITE" (attached packet #3)  
Phone to gateway:  
Tells the gateway who to add to the phone call; implements SDP in message body to dictate CODECs available

#4: "100 Trying" (attached packet #4)  
Gateway to phone:  
Acknowledges an attempt to call the specified address

#5: "183 Session Progress" with SDP (attached packet #5)  
Gateway to phone:  
Equivalent to knowing that the phone is ringing; SDP indicates selected CODEC

#6: "200 OK" with SDP (attached packet #6)  
Gateway to phone:  
Phone answered; SDP confirms/changes selected CODEC

#7: "ACK" (attached packet #7)  
Phone to gateway:  
Tells the gateway its about to send the audio UDP/RTP stream

#8-#x-1: RTP stream (example packet: attached - #8)

#x: "BYE" (attached packet #9)

Either direction:  
closes the call

To receive a call:

#3: "INVITE sip:myphonenumber" (attached packet #10)

Gateway to phone:  
Tells the phone there is an incoming call; message body includes caller ID

#4: "100 Trying" (attached packet #11)

Phone to gateway:  
Attempting to tell user there is an incoming caller

#5: "180 Ringing" (attached packet #12)

Phone to gateway:  
The phone is ringing

#6: "200 OK" with SDP (attached packet #13)

Phone to gateway:  
Phone answered, use this CODEC and talk.

#7: "ACK" (attached packet #14)

Gateway to phone:  
Time to talk.

#8: "BYE" (attached packet #15)

Either end:  
Done talking.
