1. Scanners

(a) Using ANTLR-like syntax, write a scanner for C's floating point numbers, as defined by Ritchie.

A floating constant consists of an integer part, a decimal point, a fraction part, an \( e \), and an optionally signed integer exponent. The integer and fraction parts both consist of a sequence of digits. Either the integer part or the fraction part (not both) may be missing; either the decimal point or the \( e \) and the exponent (not both) may be missing.

Hint: make sure your scanner accepts constants such as 1.0.5e-15 .3e+3 .2 1e5 but not integer constants such as 42.

(b) Draw a DFA for a scanner that recognizes and distinguishes the following set of keywords. Draw accepting states with double lines and label them with the name of the keyword they accept. Follow the definition of a DFA given in class.

```plaintext
auto case char const continue
default do double else enum if
ifelse
```

(c) Draw an NFA for a scanner that recognizes C-style multiline comments, i.e., that begin with */ and end at the next */. Make sure your DFA correctly recognizes comments such as /****/. */ */ */. Make sure your scanner accepts constants such as any character except **

(d) Convert your comment-recognizing NFA to a DFA using the subset construction algorithm.

2. Dragon book 2ed, Exercise 3.7.3, p. 166:

Construct nondeterministic finite automata for the following regular expressions using Algorithm 3.23 (p. 159, shown in class), then use the subset construction algorithm to construct DFAs for them using Algorithm 3.20 (p. 153, also shown in class).

(a) \((a|b)^*\)

(b) \(((\epsilon|a)b^*)^*\)

(c) \((a|b)^*abb(a|b)^*\)

I suggest you use text to label the states of the DFA while running the subset construction algorithm. You do not have to use the graphical style in the lecture notes.

3. Using the grammar

\[
S \rightarrow (L) | a \\
L \rightarrow L, S | S
\]

(a) Construct a rightmost derivation for \( (a,(a,a)) \) and show the handle of each right-sentinel form.

(b) Show the steps of a shift-reduce (bottom-up) parser corresponding to this rightmost derivation.

(c) Show the steps in the bottom-up construction of a parse tree during this shift-reduce parse.

4. Disambiguate and remove left recursion from the following grammar (i.e., show an equivalent grammar):

\[
e \rightarrow e >> e \mid e \mid e \rightarrow e \mid id
\]

Use C's precedence rules, i.e., the precedence of \( \rightarrow \) is higher than that of \( >> \) is higher than that of \( ? : \). Hint: make sure your grammar can accept an expression such as \( id ? id : id \rightarrow id ? id : id \) with the right precedence rules, e.g., as if it had been written \( id ? id : (id \rightarrow id) ? id : id \).
