Language Design Issues

Syntax: how programs look

- Names and reserved words
- Instruction formats
- Grouping

Semantics: what programs mean

- Model of computation: sequential, concurrent
- Control and data flow
- Types and data representation
C History

Developed between 1969 and 1973 along with Unix

Due mostly to Dennis Ritchie

Designed for systems programming

- Operating systems
- Utility programs
- Compilers
- Filters

Evolved from B, which evolved from BCPL
BCPL

Martin Richards, Cambridge, 1967

Typeless

- Everything a machine word (n-bit integer)
- Pointers (addresses) and integers identical

Memory: undifferentiated array of words

Natural model for word-addressed machines

Local variables depend on frame-pointer-relative addressing: no dynamically-sized automatic objects

Strings awkward: Routines expand and pack bytes to/from word arrays
C History

Original machine (DEC PDP-11) was very small:
24K bytes of memory, 12K used for operating system
Written when computers were big, capital equipment
Group would get one, develop new language, OS
C History

Many language features designed to reduce memory

- Forward declarations required for everything
- Designed to work in one pass: must know everything
- No function nesting

PDP-11 was byte-addressed

- Now standard
- Meant BCPL's word-based model was insufficient
Euclid’s Algorithm in C

```
int gcd(int m, int n )
{
    int r;
    while ((r = m % n) != 0) {
        m = n;
        n = r;
    }
    return n;
}
```

“New syle” function declaration lists number and type of arguments. Originally only listed return type. Generated code did not care how many arguments were actually passed, and everything was a word. Arguments are call-by-value
Euclid’s Algorithm in C

```c
int gcd(int m, int n)
{
    int r;
    while ((r = m % n) != 0) {
        m = n;
        n = r;
    }
    return n;
}
```

Automatic variable
Allocated on stack when function entered, released on return
Parameters & automatic variables accessed via frame pointer
Other temporaries also stacked
Euclid on the PDP-11

.globl _gcd
.text
_gcd:
    jsr r5, rsave
    Save SP in FP
L2:  mov 4(r5), r1
    r1 = n
    sxt r0
    sign extend
    div 6(r5), r0
    r0, r1 = m \div n
    mov r1, -10(r5)
    r = r1 \mod n
    jeq L3
    if r == 0 goto L3
    mov 6(r5), 4(r5)
    m = n
    mov -10(r5), 6(r5)
    n = r
    jbr L2
L3:  mov 6(r5), r0
    r0 = n
    jbr L1
non-optimizing compiler
L1:  jmp rreturn
    return r0 (n)
Euclid on the PDP-11

```
.globl _gcd
.text
_gcd:
    jsr r5, rsave
L2:  mov 4(r5), r1
    sxt r0
    div 6(r5), r0
    mov r1, -10(r5)
    jeq L3
    mov 6(r5), 4(r5)
    mov -10(r5), 6(r5)
    jbr L2
L3:  mov 6(r5), r0
    jbr L1
L1:  jmp rretrn
```

Very natural mapping from C into PDP-11 instructions.

Complex addressing modes make frame-pointer-relative accesses easy.

Another idiosyncrasy: registers were memory-mapped, so taking address of a variable in a register is straightforward.
The Design of C

Taken from Dennis Ritchie’s C Reference Manual

(Appendix A of Kernighan & Ritchie)
Lexical Conventions

Identifiers (words, e.g., foo, printf)

Sequence of letters, digits, and underscores, starting with a letter or underscore

Keywords (special words, e.g., if, return)

C has fairly few: only 23 keywords. Deliberate: leaves more room for users’ names

Comments (between /* and */)

Most fall into two basic styles: start/end sequences as in C, or until end-of-line as in Java’s //
Lexical Conventions

C is a *free-form* language where whitespace mostly serves to separate tokens. Which of these are the same?

1+2  
1 + 2  
foo bar  
foobar

Space is significant in some language. Python uses indentation for grouping, thus these are different:

```python
if x < 3:
    y = 2
    z = 3
```
Constants/Literals

Integers (e.g., 10)

*Should a leading – be part of an integer or not?*

Characters (e.g., ’ a ’)

*How do you represent non-printable or ’ characters?*

Floating-point numbers (e.g., 3.5e–10)

*Usually fairly complex syntax, easy to get wrong.*

Strings (e.g., "Hello")

*How do you include a " in a string?*
What’s in a Name?

In C, each name has a **storage class** (where it is) and a **type** (what it is).

<table>
<thead>
<tr>
<th>Storage classes:</th>
<th>Fundamental types:</th>
<th>Derived types:</th>
</tr>
</thead>
<tbody>
<tr>
<td>1. automatic</td>
<td>1. char</td>
<td>1. arrays</td>
</tr>
<tr>
<td>2. static</td>
<td>2. int</td>
<td>2. functions</td>
</tr>
<tr>
<td>3. external</td>
<td>3. float</td>
<td>3. pointers</td>
</tr>
<tr>
<td>4. register</td>
<td>4. double</td>
<td>4. structures</td>
</tr>
</tbody>
</table>
Objects and lvalues

Object: area of memory

lvalue: refers to an object

*An lvalue may appear on the left side of an assignment*

```c
a = 3; /* OK: a is an lvalue */
3 = a; /* 3 is not an lvalue */
```
Conversions

C defines certain automatic conversions:

- A `char` can be used as an `int`
- Floating-point arithmetic is always done with `doubles`; `floats` are automatically promoted
- `int` and `char` may be converted to `float` or `double` and back. Result is undefined if it could overflow.
- Adding an integer to a pointer gives a pointer
- Subtracting two pointers to objects of the same type produces an integer
Expressions

Expressions are built from identifiers (foo), constants (3), parenthesis, and unary and binary operators.

Each operator has a precedence and an associativity

Precedence tells us

\[ 1 \times 2 + 3 \times 4 \text{ means } (1 \times 2) + (3 \times 4) \]

Associativity tells us

\[ 1 + 2 + 3 + 4 \text{ means } ((1 + 2) + 3) + 4 \]
C’s Operators in Precedence Order

</tbody>
</table>
Declarators

Declaration: string of specifiers followed by a declarator

```
static unsigned int (*f[10])(int, char*)[10];
```

Declarator’s notation matches that of an expression: use it to return the basic type.

Largely regarded as the worst syntactic aspect of C: both pre- (pointers) and post-fix operators (arrays, functions).
Storage-Class Specifiers

- **auto**  Automatic (stacked), default
- **static**  Statically allocated
- **extern**  Look for a declaration elsewhere
- **register**  Kept in a register, not memory

C trivia: Originally, a function could only have at most three **register** variables, may only be **int** or **char**, can’t use address-of operator &.

Today, **register** simply ignored. Compilers try to put most automatic variables in registers.
Type Specifiers

int
char
float
double
struct { declarations }
struct identifier { declarations }
struct identifier
Declarators

identifier
( declarator ) Grouping

declarator () Function

declarator [ optional-constant ] Array

* declarator Pointer

C trivia: Originally, number and type of arguments to a function wasn’t part of its type, thus declarator just contained () .

Today, ANSI C allows function and argument types, making an even bigger mess of declarators.
Declarator syntax

Is int *f() a pointer to a function returning an int, or a function that returns a pointer to an int?

Hint: precedence rules for declarators match those for expressions.

Parentheses resolve such ambiguities:

int *(f()) Function returning pointer to int
int (*)(f)() Pointer to function returning int
Statements

expression;
{ statement-list }
if ( expression ) statement else statement
while ( expression ) statement
do statement while ( expression );
for ( expression ; expression ; expression ) statement
switch ( expression ) statement
case constant-expression :
default:
break;
continue;
return expression;
goto label;
label:
External Definitions

“A C program consists of a sequence of external definitions”

Functions, simple variables, and arrays may be defined.

“An external definition declares an identifier to have storage class extern and a specified type”
Function definitions

type-specifier declarator ( parameter-list )
type-decl-list
{
  declaration-list
  statement-list
}

Example:
int max(a, b, c)
int a, b, c;
{
  int m;
  m = (a > b) ? a : b ;
  return m > c ? m : c ;
}
More C trivia

The first C compilers did not check the number and type of function arguments.

The biggest change made when C was standardized was to require the type of function arguments to be defined:

Old-style                 New-style
int f();                 int f(int, int, double);

int f(a, b, c)           int f(int a, int b, double c)
int a, b;
double c;
{
}
}
**Data Definitions**

type-specifier init-declarator-list ;

declarator optional-initializer

Initializers may be constants or brace-enclosed, comma-separated constant expressions. Examples:

```c
int a;

struct { int x; int y; } b = { 1, 2 };

float a, *b, c;
```
Scope Rules

Two types of scope in C:

1. Lexical scope
   Essentially, place where you don’t get “undeclared identifier” errors

2. Scope of external identifiers
   When two identifiers in different files refer to the same object. E.g., a function defined in one file called from another.
Lexical Scope

Extends from declaration to terminating } or end-of-file.

```c
int a;

int foo()
{
    int b;
    if (a == 0) {
        printf("A was 0");
        a = 1;
    }
    b = a; /* OK */
}

int bar()
{
    a = 3; /* OK */
    b = 2; /* Error: b out of scope */
}
```
file1.c:
int foo()
{
    return 0;
}

int bar()
{
    foo(); /* OK */
}

file2.c:
int baz()
{
    foo(); /* Error */
}

extern int foo();
int baff()
{
    foo(); /* OK */
}
The Preprocessor

Violates the free-form nature of C: preprocessor lines must begin with #.

Program text is passed through the preprocessor before entering the compiler proper.

Define replacement text:

# define identifier token-string

Replace a line with the contents of a file:

# include "filename "
## C’s Standard Libraries

<table>
<thead>
<tr>
<th>Library</th>
<th>Description</th>
<th>Example</th>

Language design

Language design is library design.
— Bjarne Stroustrup

Programs consist of pieces connected together.

Big challenge in language design: making it easy to put pieces together correctly. C examples:

- The function abstraction (local variables, etc.)
- Type checking of function arguments
- The `#include` directive
