Chapter 1

Language White Paper

1.1 Introduction

DruL stands for “Drumming Language”. It is a programming language designed for composing drum music. It is common these days for drum beat composers to create drum parts using computer software (e.g. FL Studio). Creating drums parts with these programs often involves lots of tedious “pointing and clicking” (especially when making longer drum parts). DruL was designed to give the composer the ability to automate much of this tedium. There already exist other more general-purpose music programming languages (e.g. ChucK, SuperCollider, Nyquist, Haskore). These languages are complicated by note pitches, durations, and audio effects. DruL is unconcerned with these things and focuses solely on allowing the drum composer to define and manipulate beat patterns.

DruL meets the needs of algorithmic drum-composers with the beat, pattern, and clip domain-specific data-types. A pattern is essentially an object that holds binary, discrete, time-series data. At each discrete-time step, which will henceforth refer to as a beat, there is either a note or a rest. For the non-musically inclined, a note represents sound produced by the striking of a drum (or similar instrument) and a rest represents the absence of any such sound. Patterns are immutable. When a pattern is manipulated, the target pattern remains intact and a new copy is created. An instrument is one of a pre-defined set of sounds (e.g. drum notes) that can occupy a single beat. A clip is a mapping of patterns to instruments. Clips are processed in sequence as the program runs to produce output which may be audio, sheet-music notation, or a MIDI file.
DruL is mainly an imperative programming language, however it borrows ideas (map) from the functional paradigm. DruL is strictly and dynamically typed. DruL programs do not contain any loops or user-defined functions. Rather, DruL uses map and mapper defined below.

A composer typically starts a DruL program by defining some initial patterns. These patterns can then be individually processed by built-in DruL functions to produce new patterns. Alternately, the composer may define and use new functions called mappers. Composers then apply their mappers to patterns, iterating over the beats of one or more patterns at a time, building up a new pattern along the way. Once the composer has a set of patterns with which they are happy, they define their desired set of instruments (e.g. hi-hat, snare, bass drum, cowbell, etc.). With the instruments defined, the composer uses the clip construct to assign a pattern to each instrument. Finally, the clip is output to a MIDI file, playable by many multimedia players.

1.2 Language specification

There are 3 main data types in DruL: int, pattern, and clip.

Keywords are white space delimited. Indentation is not significant. Function arguments are enclosed in parentheses and comma-separated.

Anything remaining on a line after // is a comment will be ignored by the compiler.

A map takes one or many patterns, and iterates over beats on all of them at the same time, from the first beat to the last beat of the longest sequence. A map returns a pattern (that can be empty). Inside the map, per each beat, a may pattern returned which is then appended to an accumulated pattern. This accumulated pattern is then returned by the map after the final iteration.

\[
\begin{array}{llll}
\text{return} & \text{rand} & \text{clip} & \text{mapper} \\
\text{if} & \text{pattern} & \text{instrument} & \text{print} \\
\text{elseif} & \text{concat} & \text{map} \\
\text{else} & \text{true} & \text{false} \\
\end{array}
\]

Scopes: There is a general scope, and one scope per map. Variables in the general scope can be seen from within a map, but not written to. Variables defined in a map are garbage collected at the end of the map.
1.3 Quick tutorial

In this section we give examples of what DruL code will look like, in the form of a tutorial.

1.3.1 Integers

Integers are part of our language.

\[
\begin{align*}
a &= 3; \\
b &= a + 2; \\
c &= b * 12;
\end{align*}
\]

1.3.2 Pattern

Patterns are the data type the programmer will likely spend most of their time dealing with. For convenience, the programmer can supply a string constant made up of 1s and 0s, which will be translated into a pattern: if the character is a 1, there is a note on the corresponding beat; if 0, a rest.

\[
p1 = \text{pattern}("101010");
\]

Patterns can be concatenated to form new patterns:

\[
\text{pcat} = \text{concat}(p1, \text{pattern}("111000"), \text{pattern}("1"));
\]

\text{pcat} will be equal to 1010101110001.

There is also a shortcut to concatenate the same pattern many times:

\[
\begin{align*}
\text{pcat2} &= \text{concat}(p1, p1, p1); \\
\text{pcat3} &= \text{pattern}("101010").\text{repeat}(3); \\
\text{pcat4} &= p1.\text{repeat}(3);
\end{align*}
\]

\text{pcat2}, \text{pcat3}, and \text{pcat4} are all equivalent.
1.3.3 Map

Of course, we will not hardcode every pattern we want to create. We use map to create meaningful new patterns from existing ones:

\[
p2 = \text{map}(p1)\\\{\\\text{if ($1.\text{note}()) \{ \text{return \ pattern("11")}; \}}\\\text{else} \quad \{ \text{return \ pattern("0");} \}\\\};\\n\]

This will create the following pattern: 110110110. The goal of a map is to easily iterate over a pattern. \textit{p1.note} returns \textit{true} if there is a note on the current beat, \textit{false} otherwise. If you call map on multiple patterns that are not of the same length, the shorter patterns will be padded with \textit{NULL} beats.

1.3.4 Mapper

For ease of use, you can define a \textit{mapper} that contains the behavior used by \textit{map}. We create \textit{p3}, which is the same as \textit{p2}:

\[
\text{mapper myMapper(p)}\\\{\\\text{if (p.\text{note}) \{ \text{return \ pattern("11")}; \}}\\\text{else} \quad \{ \text{return \ pattern("0");} \}\\\};\\n\]

\textit{p3} = \textit{map}(p1) myMapper;

\textit{mapper} will be very important when building a standard library for the language.

1.3.5 More complex examples

Now that we have a proper syntax, let’s get to more complicated examples. We introduce 2 new features that can be used inside a \textit{map}: \textit{prev} and \textit{next}. They give
you access to earlier and later beats in a pattern, using the syntax \texttt{p.prev(n)} and \texttt{p.next(n)}. Also, for a pattern \( p \), \( p.rest() \) is true if and only if we did not reach the end of this pattern.

**reduction**: accelerate by cutting one beat out of two

\[
downbeats = \text{pattern}("1001000100010000")
\]
\[
alternate\_beats = \text{pattern}("10")\cdot\text{repeat}(8)
\]
\[
downbeat\_diminution = \text{map}(downbeats, alternate\_beats)
\]
\[
\begin{cases}
  \text{if } ($2$.rest()) \{ \text{return pattern}("\""); \} & \text{// pattern of length 0} \\
  \text{elseif } ($1$.note()) \{ \text{return pattern}("1"); \} \\
  \text{else} \{ \text{return pattern}("0"); \}
\end{cases}
\]

output is: 10101010.

**improved reduction**: putting a rest (0) only if the 2 original beats were rest

\[
\text{one\_and\_four} = \text{pattern}("1001100110011001")
\]
\[
alternate\_beats = \text{pattern}("10")\cdot\text{repeat}(8)
\]
\[
improved\_diminution = \text{map}(\text{one\_and\_four}, alternate\_beats)
\]
\[
\begin{cases}
  \text{if } ($2$.rest()) \{ \text{return pattern}("\""); \} \\
  \text{elseif } ($1$.note()) \{ \text{return pattern}("1"); \} \\
  \text{elseif } ($1$.next(1).note()) \{ \text{return pattern}("1"); \} \\
  \text{else} \{ \text{return pattern}("0"); \}
\end{cases}
\]

1.3.6 Instruments and Clips

Now that we have a large and varied collection of patterns, we can show how to combine those patterns into clips.

Before we define any clips, we must tell the compiler what instruments they will use. This can only be done once per program, and uses the \texttt{instruments} function:

\[
instruments("hihat", "bassdrum", "crash", "snare");
\]
Once the instruments are defined, we can create a clip from our existing patterns, using an associative-array notation:

```
clip1 = clip
    (  
      "bassdrum" <- downbeats,  
      "hihat"    <- alternate_beats
    );
```

The same result can be achieved by simply listing the patterns for each instrument in the order they are defined in the `instruments` declaration:

```
clip2 = clip
    (  
      alternate_beats,  
      downbeats          
      // remaining instruments have an empty beat-pattern
    );
```
Chapter 2

Tutorial

2.1 Introduction

In this section we present some quick tutorials that explain the main features of DruL language. We start with the basics: “Hello World” is in Section 2.2.1, integers and if/else are shown in 2.2.2 and finally patterns are introduced in 2.2.3. That being done, we learn how to combine patterns (2.3), manipulate patterns (2.4) create a named mapper (2.5), create a clip (2.6), and finally how to bring all this together and create a sheet of music (2.7).

2.2 The Very Basics

The drul command can take DruL code either from the standard input or as a file specified on the command line (drul mysource.drul). Examples in this section should work equally well if passed in either way.

2.2.1 Say hello!

Because it is traditional, albeit almost completely irrelevant to this language, here is our first DruL program:

print ("hello, world!");
This will print the string “hello, world!” to the standard output, on a line by itself. Note that unlike many languages, DruL does not require you to place a newline character at the end of a string to have it print on a single line (conversely, it gives you no method to print without a newline at the end).

### 2.2.2 Fundamentals

Variables in DruL must have names that begin with a letter or underscore, and contain only letters, numbers, and underscores thereafter. Variables are dynamically typed and scoped, so to create one, you need only assign a value to it:

```plaintext
a = 350;
b = 300;
print(a + b);
```

This should print out the number “650”, again on a line by itself.

Now, with some variables defined, we can proceed quickly through the rest of the features that you might guess are present from the above:

```plaintext
a = 350;
b = 300;
c = b - a;
d = a % b;
e = 60 / d;
if (e > 1) {
    print("this is what you might expect to have happen");
} else {
    print("but this is what actually prints");
}
```

Why does the second line print, and not the first? DruL’s types do not include floating-point numbers, so all arithmetic is done using integers, and non-integral results are truncated (as is done in C and other related languages) to their integer parts.
2.2.3 One more variable type: patterns

We will now introduce the first data type that distinguishes DruL from most other languages: the pattern. A pattern is a sequence of true/false values, telling the drummer (or MIDI sequencer) whether or not to play on a particular beat. They are created using the \texttt{pattern} function:

\begin{verbatim}
  p1 = pattern ("" ); // empty pattern (length 0)
  p2 = pattern ("0" ); // pattern with only one 'rest' in it.
  p3 = pattern ("1" ); // pattern with only one 'note' in it.
  p4 = pattern ("100100100" );
\end{verbatim}

Each time a “1” appears in the string you pass to \texttt{pattern}, the resulting pattern carries the instruction to play on that beat; when a “0” appears, the pattern contains a rest. You may notice that we also have explanatory comments in this code: comments in DruL begin with “//” and continue to the end of the current line (there are no multi-line comments).

To see the contents of a pattern you have created, you can always just print it out:

\begin{verbatim}
  p = pattern ("100100100" );
  print (p );
\end{verbatim}

2.3 Combining Patterns

Once you have a pattern or two, DruL gives you several ways to build new ones. Using the \texttt{concat} function, you can combine them end-to-end:

\begin{verbatim}
  catenated = concat ( 
    p1 , 
    pattern ("11110000" ), 
    pattern ("00011" ) 
  );
\end{verbatim}

Notice that we have broken up the arguments to \texttt{concat} onto multiple lines for ease of reading–since DruL is a free-form language, any amount of whitespace can appear any place that any whitespace is allowed.

Pattern objects also have a \texttt{repeat} method, which produces a new pattern containing all the beats and rests of the original, repeated however many times the method is
given as its argument. (In fact, you can give it an argument of 0 to return an empty pattern, though there are less obscure ways to do that.)

\[ p_{\text{custom}} = \text{concat}( \]
\[ \quad p2, \]
\[ \quad p3.\text{repeat}(2), \]
\[ \quad p4.\text{repeat}(3), \]
\[ \quad p3.\text{repeat}(2), \]
\[ \quad p4.\text{repeat}(4) \]
\[ ) ; \]

2.4 Manipulating Patterns

Patterns also have methods that allow you to produce new patterns that are not simply combinations of old ones laid end to end.

Using the `reverse` method, you can turn a pattern back to front; using the `slice` method, you can extract just the portion of it you want:

\[ \text{bassackwards} = \text{catenated} . \text{reverse}(); \]
\[ p_{\text{new}} = \text{bassackwards} . \text{slice}(4,10); \]

The arguments to `slice` tell DruL which is the first beat of the pattern that you’re interested in, and how many beats (including that one) you would like. So to the call above will produce a pattern 10 beats long, that starts with the 4th beat of `bassackwards`. If you ask for more beats than the pattern has, then `slice` will return a pattern that starts on the beat you specify and continues until the end of the original pattern.

Since all of these methods return patterns, and are methods of patterns, you can also stack your method calls into one statement:

\[ p_{\text{new}} = \text{catenated} . \text{reverse}() . \text{slice}(4,10); \]

But the most powerful mechanism for creating new and different patterns is the `map` function. This is how to take a pattern and create its complement: a pattern that has a rest everywhere that the original has a note, and vise-versa:
reversed = map (p_new) {
    if ($1.rest()) { return pattern("1"); }  
    else { return pattern("0"); } 
};

The map function moves from beat to beat of the pattern it is passed, setting the variable $1 to the point to the current beat of the first (and in this case, the only) pattern in its argument list. After each step, it stores the value that is returned, and in the end, it concatenates all these patterns together to form the new pattern that is created by this map.

You might be wondering, at this point, if it is legal to return a pattern that is longer or shorter than one beat. The answer, happily, is “yes!” To produce, for example, a pattern that has an extra rest inserted after every note, we could do this:

new_pattern = map(old_pattern) {
    if ( $1.note() ) { return pattern("10"); } 
    return $1; 
};

You may notice that we didn’t bother to create a pattern for the second case: if we simply want to return a single-beat pattern with the same value (beat or rest) as the current beat of one of our input patterns, we can simply return that beat, and DruL will interpret it correctly.

Finally, we can pass more than one pattern to a mapper, and use variables $2, $3 and so forth. This mapper takes two patterns as its arguments, and produces a new pattern that contains the portions of the first pattern that occur in parallel with notes (not rests) in the second pattern:

old_pattern = pattern("10101100");
filtered_pattern = map(old_pattern, pattern("1110011110000")) {
    if ( $2.note() ) { return $1; } 
};
print(old_pattern);

In this case, the printed value will be “101100” (if no return statement is found, map assumes that you meant to return an empty pattern). The same result could be achieved using a series of calls to slice and concat, but this is a much more flexible method.
If one of the patterns passed to `map` is longer than the others, `map` will continue until it reaches the end of the longest pattern—the beats of the patterns that have already ended are considered to be neither notes nor rests (and will return false if either of those methods is called).

We've mentioned beats as if they were objects once or twice, and in fact they are—you can't create them directly, but `map` does it for you. You've seen two of the methods you can call on beats (note and rest, but there are two more that make `map` even more powerful: prev and next. Calling prev with an integer argument returns the beat in the same pattern from that many beats ago in the pattern (and you can probably guess how next works). These beats may be from before the beginning or after the end of the pattern, in which case they behave just as described in the previous paragraph: both the note and rest methods will return false.

```plaintext
new_pattern = map (old_pattern) {
  if ( $1.note() && $1.prev(1).note() ) { return $1; }
  else { return pattern(""); }
}
```

### 2.5 Named mappers

In all of the examples so far, we have simply supplied the `map` function with a block of statements to run for this particular set of patterns. This block is what we refer to as an “anonymous mapper.” In reality, of course, it is likely you would want perform the same type of transformation on more than one pattern (or set of patterns). To do this without annoying repetition of code, you can define a named mapper, then use the name instead of the code block. The named mapper can also have named parameters, which may be easier to keep track of than the shell-like variables used in anonymous mappers. This allows us to re-write the previous example in a somewhat more readable way:

```plaintext
mapper filter_map ( input_pattern , filter_pattern ) {
  if ( filter_pattern.note() ) { return input_pattern; }
}

filtered_pattern =
  map (old_pattern, pattern("111001110000"))  filter_map;
```
2.6 Assembling clips

Now that we have a bunch of patterns, the next thing to do with them is assemble them into pieces of music, where each instrument has a (presumably) different pattern to play. Before we do that, however, we have to define what instruments we are using. This is done using the `instruments` function (which isn't actually a function at all, but we're going to ignore that for now–see section 3.7.1 in the Language Reference Manual if you want the grizzly details).

```javascript
instruments("hihat","bassdrum","crash","snare");
```

If you want to use the default instruments, you can simply call `instruments` with no arguments, but you have to call it once (and exactly once) before you get to the next step: using the `clip` function to bring all of your patterns into one place.

```javascript
my_first_clip = clip(  
  "hihat" <- pattern("00100010"),  
  "bassdrum" <- pattern("10001000"),  
  "crash" <- pattern("10000000"),  
  "snare" <- pattern("01110111")
);
```

Of course, this is a little verbose—if you're specifying the patterns in the order they appear in the instrument definition list, you can just pass the patterns you want as arguments, instead of using the fancy syntax above:

```javascript
my_first_clip = clip(  
  pattern("00100010"),  
  pattern("10001000"),  
  pattern("10000000"),  
  pattern("01110111")
);
```

2.7 The Big Payoff

Now that we know how to assemble patterns into a song, all that’s left is to see what our song looks like when we bring it back to the outside world. There are three easy ways to do this (other, of course, than a simple `print` call). First, you can call the `outputText` method to print your song to a text file:
instruments();  // default instruments: hi-hat, snare, kick-drum and cowbell

song = clip(
    pattern("00100010"),
    pattern("01110111"),
    pattern("10001000"),
    pattern("10000000")
);

song.outputText("my_song.txt");

If you have the midge program installed, you can also convert it directly into a
MIDI file you can play using many music players:

tempo = 120;
song.outputMidi("my_song.mid", 120);

And finally, you can output to the format used by the typesetting package Lilypond to
produce beautifully typeset sheet music:

song.outputLilypond("my_song.ly", "Title of the Song");

Assuming you have Lilypond installed, this allows you to produce PDF sheet music that
looks roughly like this:

http://www.undef.org.uk/code/midge/
http://www.lilypond.org/
Title of the Song

hh_c  sd_ac  bd  cowbell

Congratulations! You’re done with the tutorial–have fun with DruL!
Chapter 3

Language Reference Manual

3.1 Introduction

DruL is mainly an imperative programming language, however it borrows ideas (map and filter) from the functional paradigm. In addition to integers, DruL’s main datatypes are pattern and clip. Instruments are defined as constants.

DruL programs do not contain any loops or user-defined functions. All pattern and clip creation and manipulation is done using the map construct described below.

3.2 Lexical Conventions

3.2.1 Comments

Comments in DruL start with the token “//” and continue until the end of the current line. DruL has no multi-line comment syntax.

3.2.2 Whitespace

Space, tab, end of line, and return are all considered the same and their only use is to separate tokens.
3.2.3 Characters

DruL uses the ASCII character set.

3.2.4 Identifiers

An identifier consists of any uppercase or lowercase character or an underscore, followed by any sequence of uppercase or lowercase characters, underscores, and digits (0 through 9). The maximum length of an identifier is 64 characters.

In addition, within the context of a mapper, special variables $1$ through $n$ (where $n$ is the number of patterns passed to the mapper) are defined as read-only aliases (see section 3.6.2 for more details on this feature).

All identifiers in a given scope, be they mapper names, variables, or built-in functions, belong to a single namespace.

3.2.5 Keywords

```
return  rand  clip  mapper
if      pattern  instrument  print
elseif  concat  map
else    true    false
```

3.3 Types

There are 3 basic types in DruL: integers, patterns, and clips. In addition, ‘string’ constants may be used in DruL source code, but there is no variable type to which they can be directly assigned. Likewise, boolean expressions exist, but cannot be assigned to variables. Values in DruL are strongly typed, but the type of a variable is determined dynamically.
3.3.1 integer

All integers are base 10, and may optionally be preceded by a sign (+ -). Any sequence of digits (0 through 9) is valid. Leading 0s are ignored, so a sequence such as 0000123 is interpreted as 123. Integers are mutable.

rand is a function that returns a non-negative number. It either accepts a positive integer argument, in which case it returns a random number between 0 (inclusive) the argument (exclusive), or no argument in which case rand returns either 0 or 1.

```cpp
r = rand();
s = rand(19);
```

3.3.2 pattern

A pattern is essentially an object that holds binary, discrete, time-series data. At each discrete-time step, which will henceforth be referred to as a beat, there is either a note or a rest. For the non-musically inclined, a note represents sound produced by the striking of a drum (or similar instrument) and a rest represents the absence of any such sound. Patterns are immutable. When a pattern is manipulated, the target pattern remains intact and a new copy is created. The length of a pattern can be any non-negative integer.

3.3.3 beat

A beat is a lightweight object that cannot be created directly by the user: it exists only within a mapper (for more discussion of which, see section 3.6.2 below). It gives direct access to information about a single beat of a pattern object (including the beats surrounding it).

3.3.4 clip

An instrument is one of a pre-defined set of sounds (e.g. drum notes) that can occupy a single beat. A clip is a mapping of patterns to instruments. Clips are processed in sequence as the program runs to produce output which may be plain-text or a MIDI file. Clips are immutable.
3.3.5 string

A string constant begins with an ASCII double-quote character, continues with an arbitrary sequence of ASCII characters other than \, ", and the ASCII newline character, and concludes with another " character. If a \ or " character is desired, it can be escaped using the \ character.

3.4 Statements

In the most common case, a statement consists of a single expression followed by a semicolon (";"). Importantly, unlike many languages with similar syntax, DruL does not consider a block to be equivalent to a statement. Instead, statements in DruL take one of the six forms below.

3.4.1 Expression Statements

The basic form of statement, as in most C-like languages, is the expression statement:

expression-statement: expression;

The precedence table for operators in DruL is given here:

<table>
<thead>
<tr>
<th>Operators</th>
<th>Notes</th>
<th>Associativity</th>
</tr>
</thead>
<tbody>
<tr>
<td>.</td>
<td>Method call</td>
<td>left to right</td>
</tr>
<tr>
<td>− !</td>
<td>Unary minus and logical negation</td>
<td>right to left</td>
</tr>
<tr>
<td>* / %</td>
<td>Standard C meanings</td>
<td>left to right</td>
</tr>
<tr>
<td>+ −</td>
<td>Addition/subtraction</td>
<td>left to right</td>
</tr>
<tr>
<td>&lt; &lt;= &gt; &gt;=</td>
<td>Standard C meanings</td>
<td>left to right</td>
</tr>
<tr>
<td>!= ==</td>
<td>Standard C meanings</td>
<td>left to right</td>
</tr>
<tr>
<td>&amp; &amp;</td>
<td>Standard C meaning</td>
<td>left to right</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

The sections that follow use the model of the C Language Reference Manual to indicate the various types of expression. As in that example, the highest-precedence forms of expression are listed first. Since much of the material below is extremely straightforward, plain-English descriptions are supplemented by grammatical descriptions only when necessary.
**Primary Expressions**  A primary expression consists of a constant (integer or string), an identifier, or a parenthesized expression.

**Function, Method, and Mapper calls**  Arguments to functions, methods and mappers are evaluated in applicative order, left to right within a given list. (Arguments are also passed by value, not by reference.) Depending on the function or method in question, functions and methods may return values of any type, including boolean values (which cannot be assigned to variables); mappers, by their nature, always return patterns.

```
arglist: ( expression ) | ( expression , arglist )
method-call : identifier . identifier arglist
function-call : identifier arglist
mapper-call: map arglist mapper
mapper : identifier | block
block : { statement-list }
statement-list: statement | statement statement-list
```

**Unary operations**  The unary operations in DruL are arithmetic and logical negation (unary − and !). Since DruL is strictly typed, arithmetic negation can only be applied to integer values, and logical negation to boolean values.

**Standard arithmetic operations**  Expressions may use the standard binary arithmetic operators (+, −, *, and /), with their standard precedence. It is required that both of the operands in such an expression be integer values.

**Comparison operations**  As in most C-family languages (and as shown in the precedence table above), relational operators have precedence over equality tests. These operators return boolean values, which can be used in if statements but cannot be assigned to variables.

Relational tests may be used on integer values only; equality tests can be used on variables of any type, but in the case of patterns and clips, they will only report
whether the two variables being tested are aliases of the same object, not any deeper notion of equivalence.

**Logical combination operations** Here again we follow the conventions of C, and give && precedence over ||. These operators require their operands to be boolean values, and return boolean values.

### 3.4.2 Assignment Statements

Assignment in DruL is not a simple operator to be placed in the middle of an expression. Rather, it is a separate type of statement, which may appear anywhere another statement may appear.

\[
\text{assignment-statement: identifier} = \text{expression-statement}
\]

Assignment is polymorphic: the same syntax is used to assign variables to integers, patterns and clips. Furthermore, due to DruL’s dynamic typing, a variable may be reassigned to a different type.

### 3.4.3 Selection Statements

Selection statements in DruL take the following form: the string `if`, followed by an expression that returns a boolean result, enclosed in parentheses, followed by an open-brace (“{”), one or more statements, and a close-brace (“}”). This may optionally be followed by one or more `elseif`s, which are also followed by parentheses and a block of statements, and one (optional) `else`, which omits the test expression but is also followed by a block of statements.

\[
\text{selection-statement : if ( boolean-expression ) block if-tail}
\]

\[
\text{if-tail : } \epsilon | \text{if-middle} | \text{if-middle else } \{ \text{statement-list } \}
\]

\[
\text{if-middle : } \epsilon | \text{elseif ( boolean-expression ) } \{ \text{statement-list } \} \text{ if-middle}
\]
3.4.4 Mapper Definition Statements

A mapper definition consists of the word Mapper, followed by an identifier, followed by a parenthesized list of comma-separated identifiers, followed by a block.

mapper-definition : mapper identifier namelist block

namelist: ( identifier ) | ( identifier , namelist )

3.4.5 Return statements

A return statement can only appear inside the statement block of a named or anonymous mapper:

return : return expression

If this statement is reached, the value of expression will be the output of this iteration of the mapper block. Accordingly, this expression must evaluate to either a pattern or a beat value.

3.4.6 Instrument definition

This is a special statement that closely resembles a function call:

instrument-definition: instruments ( arglist )

The arguments to this pseudo-function must all evaluate to strings. See section 3.7.1 for a detailed discussion.

3.5 Blocks, namespace and scoping

3.5.1 Blocks

DruL has a limited block structure: only in the context of an if/elseif/else sequence or a Mapper Definition statement is a new block needed or allowed. In these cases, curly braces (“{}”) are used to delimit the statement-sequence that falls within the block, and they must contain one or more statements.
Mapper definitions define a new closed scope (one from within which externally defined variables are not visible); if blocks do not define a new scope, so all variables used within them are visible to the enclosing block, and vice-versa.

### 3.5.2 Namespace

DruL has one namespace shared by variables, built-in functions and mapper names. Additionally, each type has an associated namespace for methods. Technically speaking, mappers are values like any other, and their names can be re-used, but this is strongly discouraged.

### 3.5.3 Scoping

Variables in DruL are dynamically scoped. DruL has one top level scope, and one scope for each mapper that the program enters (named or anonymous). Mappers may call each other (or themselves) recursively, and may be defined within other mappers, so a hierarchy of substantial depth can (in principle) be achieved. Within each scope, a program has read-only access to all variables and mapper names defined in the scopes above it in this hierarchy: attempts to assign to a variable from an outer scope will produce a new variable in the inner scope, which masks the original variable.

### 3.6 Patterns and pattern operations

#### 3.6.1 Patterns

A pattern is a sequence of beats. Each beat can be a note or a rest. To define a pattern, DruL uses ‘0’ for rests and ‘1’ for notes. A pattern can be created in the following way:

```druL
p1 = pattern("101010");
```

which represents the sequence note, rest, note, rest, note, rest. Its length is 6.

There are built-in functions and methods on patterns included in DruL.
Patterns can be concatenated to form new patterns. The `concat` function can take any positive number of pattern arguments. Patterns are concatenated from left to right.

```java
pcat = concat(p1, pattern("111000"), pattern("1"));
```

`pcat` will be equal to 10101110001.

The `repeat` method is a shortcut to concatenate the same pattern many times:

```java
pcat2 = concat(p1, p1, p1);
pcat3 = pattern("101010").repeat(3);
pcat4 = p1.repeat(3);
```

Note that `pcat2`, `pcat3`, and `pcat4` are all equivalent.

The `length` method gives the length of a pattern.

```java
len = p1.length();
```

The value of `len` is 6.

The `slice` method gives you a subpattern from a pattern. It takes two arguments: first is index (starting at 1) and second is length of the desired subpattern. Requesting a subpattern out of range will raise an error. Example:

```java
psub = pattern("101010").slice(2, 3);
```

`psub` is “010”.

The `reverse` method returns the reverse of a pattern. It doesn’t take any arguments.

```java
preverse = pattern("111000").reverse();
```

`preverse` is “000111”.

Finally, you can have an empty pattern of length 0:

```java
p8 = pattern("");"
3.6.2 Map

The map construct is used to create new patterns from existing ones. map performs an operation iteratively on a set of patterns. The beats in the patterns are iterated over from left to right. The output of a map is a new pattern. For example:

```dru
p9 = pattern("101");
p10 = map(p9) {
    if ($1.note()) { return pattern("11"); }
    else { return pattern("0"); }
};
```

p10 is “11011”.

map takes a sequence of pattern arguments and followed by a mapper function. In the above example the mapper function is defined anonymously within curly braces. Within a mapper function, the current beat of each pattern argument is aliased to the special mapper variables $1, $2, $3... and so on. This notation is mandatory in anonymous mapper functions such as the example above. If you use $N while there is fewer than N arguments, DruL will raise an error.

DruL uses the beat methods note, rest and null to check whether the current beat is a note, a rest, or null. $1.note returns true if there is a note on the current beat in the first pattern argument, and false otherwise.

One can use the beat method asPattern to convert as beat to a pattern. This way, one can then make use of functions and methods of patterns. For example:

```dru
p11 = map( pattern("1111") ) {
    return concat($1.asPattern(), pattern("0"));
};
```

p11 is “10101010”.

DruL uses the beat methods prev and next to access the previous and following beats of the pattern to which a given beat belongs. These methods can be passed a single argument which specifies how far forward or back in the pattern to go. For example:
\texttt{p12 = map( pattern("1101") )}
{  
\hphantom{.} if ($1$.note() && $1$.next(1).note()) { return pattern("1"); }  
\hphantom{.} else { return pattern("0"); }  
};

\texttt{p12 is "1000".}

\texttt{next} may return a \texttt{NULL} beat as it does when called in the last iteration of the above example. When used with a \texttt{NULL} beat, both the \texttt{note} and \texttt{rest} methods will return \texttt{false}.

If you call \texttt{map} on multiple patterns that are not of the same length, the shorter patterns will be padded with \texttt{NULL} beats.

By default, an empty pattern is returned for each iteration.

Each new pattern constructed by \texttt{map} begins as an empty string. As the pattern arguments are iterated over, the return values of the mapper function (which are also patterns) are concatenated onto the end of the new pattern.

Variables defined in a mapper function are garbage collected at the end of the map.

\section*{3.6.3 Mapper}

Mapper functions may also be defined with a name, to be used elsewhere in the program.

For example, the above example could have been written in the following way:

\texttt{mapper myMapper(p)}
{  
\hphantom{.} if (p.note() && p.next(1).note()) { return pattern("1"); }  
\hphantom{.} else { return pattern("0"); }  
};
\texttt{p12 = map(pattern("1101")) myMapper;}

Recall from section \[3.4.4\] that a Mapper definition includes a name for the mapper and a \texttt{namelist} of formal arguments. When a named mapper is used in a \texttt{map} call,
each pattern that is passed to the map is associated with the corresponding name in the namelist in the mapper’s definition. Then, within the body of the mapper, the current beat of each pattern is aliased to that name, as well as to “$n”.

A mapper function must be defined before it is used.

### 3.7 Clips

#### 3.7.1 Instruments

Before we define any clips, we must tell the compiler what instruments they will use. This can only be done once per program, and uses the instruments function. (Technically speaking, this is not a function but a special statement type that uses a function-like syntax. The distinction is largely academic, however.) This function can take a variable number of arguments. Each argument is the name of an instrument to be defined. In the example below, four instruments are defined:

```plaintext
instruments('hihat','bassdrum','crash','snare');
```

Instruments must be defined before any clips have been defined. This function can only be called once. Also, it cannot be called from inside a mapper.

#### 3.7.2 Clips

A clip represents a collection of patterns to be played in parallel, where each pattern is played on a single instrument.

Once the instruments are defined, we can create a clip from our existing patterns, using an associative-array notation:

```plaintext
clip1 = clip
(  "bassdrum"  <- downbeats,
  "hihat"     <- alternate_beats
);
```
The same result can be achieved by simply listing the patterns for each instrument in the order they are defined using the `instruments` function:

```python
clip2 = clip
    (alternate_beats, downbeats
      // remaining instruments have an empty beat-pattern
    );
```

The patterns passed into clips are passed by value, not by reference.

Clips also have a small selection of output methods, discussed in the section below.

### 3.8 Outputs

DruL has two kinds of outputs: any data structure can be printed to standard output for debugging purposes, and clips may be output into files as text or using some more complex representation, such as MIDI or Lilypond (for PDF conversion).

#### 3.8.1 Standard output

The `print` statement displays any type to the standard output, including strings. For example:

```python
print("DruL");
print(pattern("01"));
```

The representation of a string is the string itself. The representation of a pattern is the string that would have been used to initialize the pattern. For example, if we have a pattern

```python
p = pattern("01").repeat(2);
print(p);
```
The output is "0101";

The **print** function always include a platform-appropriate line ending.

### 3.8.2 Text file

Using the same format as is used by **print**, DruL can print a text representation of a clip to a file using the **outputText** method of the clip:

```javascript
myClip.outputText("myfile.txt");
```

The file being written to is truncated if it exists, and created if it does not exist.

### 3.8.3 MIDI file

The method **outputMidi** works similarly, but in addition to the filename, it requires a tempo for the MIDI file to be produced (in beats per minute—this must be a positive integer).

```javascript
myClip.outputMidi(‘myfile.mid’,120);
```

The transformation from clip to MIDI may rely on external libraries like MIDGE[^1]. There is no guarantee on which of the three existing MIDI formats is used. DruL tries to match its instrument definition with MIDI instruments definitions using the names. If no match can be found, DruL will use a default MIDI instrument (first one is cow bell).

### 3.8.4 Lilypond file

The clip method **outputLilypond** operates similarly to the above, but takes a title (to be printed at the top of the page of typeset music) as an optional second argument:

myClip.outputLilypond('myfile.ly', 'My New Drum Loop');

For best results, the resulting Lilypond file will need to be typeset using an external program (Lilypond, one presumes).
Chapter 4

Project Plan

4.1 Processes

Almost all planning and decision making was done as group. The team leader resolved only very few disagreements of less importance, on which spending the time to come to a consensus was not warranted. As explained in more detail in section 4, we made liberal use of paired programming and most coding was done in group sessions. Documentation, including the Reference Manual and this report, was mostly done individually; each team member solely responsible for specific sections. Our testing process made use of an automated test-suite. After each change to the code base, the regression tests were all run, making sure that the number of tests passed always increased. This was somewhat done in the spirit of test driven development, as we made many test cases for language features before they were implemented, and used the test cases as a “ToDo” list. Our development process was also in the spirit of Agile or Extreme Programming. We started with a minimal, yet functioning language, and incrementally added features to it, all the while maintaining a working system.

Our plan was to complete tasks in the following order, working on tasks in parallel where possible:

1. Design DruL
   - Specify syntax
   - Specify semantics
2. Write the LRM

3. Implement Basic Building Blocks
   • AST
   • Scanner
   • Parser
   • Test Suite Driver
   • Initial test cases
   • Basic Interpreter (with evaluate, execute, and built-in print for string literals)

4. Implement Generic Language Features
   • Integer arithmetic
   • Boolean operations
   • Assignment statements and symbol table
   • Selection statements

5. Implement Core DruL Language Features
   • Pattern creation and printing
   • Pattern built-in functions and methods
   • Map, mappers, and beats
   • Named mappers
   • Beat built-in methods
   • Instrument definition
   • Clip creation and printing

6. Implement Advanced DruL Language Features
   • Clip text output
   • Clip MIDI output
   • Clip Lilypond output
   • Clip built-ins concat and repeat (not implemented)

7. Implement Fit and Finish
   • Interpreter command-line arguments
• Detailed error messages
• Error message line numbers
• Trapped parse errors
• Static semantic checks (not implemented)

We initially used our own SVN server for source and documentation management. However, we soon moved to Google Code to make used of its issues list for keeping track of bugs and the ToDo’s correpsonding to the above features.

4.2 Style Guide

Due to the fact that all of our team members started as novice OCaml programmers and OCaml’s syntax is unlike any languages our team was already familiar with, we lacked much intuition regarding good OCaml coding style. However, over the course of our coding, the following coding practice emerged:

• Use hard tabs for indentation
• Specify pattern matched arguments and use “match with” syntax instead of the “function” shorthand for pattern matching
• Encapsulate each “match with” clause in parentheses
• Put each match case on a new line
• Indent each match case and put a tab after the “—” separator
• Begin results of a match case on the same line as the “-¿”
• Indent subsequent lines of the results of a match case
• Horizontally align similar lines of code using extra whitespace

We never reached a consensus on whether to make our OCaml identifiers CamelCase or underscore separated.

4.4 Roles and Responsibilities

Each team member volunteered for the completion of tasks. Tasks were not divied up amongst team members in advance. Rather, after team members finished their tasks they simply discussed what they should (or would like to) work on next with the rest of the team. Many tasks (especially the more difficult ones) were tackled in pairs. We found having an extra pair of eyes examining code and documentation as it was being written (i.e. paired programming) drastically cut down on the number of initial bugs and the amount of refactoring done later.

Below is a general description of the major tasks completed by each team member. Paired efforts are noted in parentheses. Note, that most work was with the group all in one room at one common table. This allowed and individual or pair to ask for help or advice from the rest of the team. This is done consistently and resulted with all members of the team being at least somewhat familiar with the implemenation of almost all parts of the system.

- Rob:
  1. As team leader, resolved minor conflicts
  2. Proposed drumming language idea
  3. Setup initial SVN repository
  4. Wrote introduction for all documents
  5. Assisted with language design
  6. Wrote the Pattern, Map, and Mapper sections of the LRM
  7. Coded the AST (with Ben)
  8. Assisted with coding the parser
  9. Coded the initial “helloworld” interpreter (with Waseem)
  10. Coded pattern construct (with Ben)
  11. Coded DruL’s built-in functions and methods and added corresponding test cases (with Waseem)
  12. Coded instrument and clip constructs (with Theirry)
  13. Performed built-ins code refactoring (with Ben)
  14. Performed code cleanup
  15. Refactored text output
16. Coded MIDI output
17. Wrote an example drum song using DruL
18. Edited all the presentation slides
19. Wrote the Project Plan section of the report

• Ben:
  1. Decided on map/mapper idea
  2. Assisted with writing proposal
  3. Assisted with language design
  4. Wrote the Types, Statements, Blocks and Scoping sections of the LRM
  5. Coded the AST (with Rob)
  6. Assisted with coding the parser
  7. Coded the parse-tree dumper
  8. Coded selection and assignment statements
  9. Coded pattern construct (with Rob)
 10. Coded map and mapper (with Thierry)
11. Coded GCD implementation using DruL
12. Refactored built-ins (with Rob)
13. Refactored interpreter into smaller files
14. Refactored scanner, parser, and interpreter to include line numbers in error messages (with Thierry)
15. Added tests for error messages
16. Coded Lilypond output
17. Refactored output code
18. Fixed corner-case symbol-table bugs
19. Wrote parts 1 and 2 of the presentation (except for the mapper animation)
20. Updated the LRM for the report (with Waseem). Wrote the tutorial section of the report (with Waseem)

• Thierry:
  1. Assisted with writing proposal
  2. Assisted with language design
  3. Wrote the Instrument, Clip, and Output sections of the LRM
4. Setup replacement Google Code repository
5. Coded the test-suite driver
6. Manually created initial suite of test input and corresponding output files
7. Assisted with coding the parser
8. Coded map and mapper (with Ben)
9. Coded named mapper
10. Coded instruments and clip constructs (with Rob)
11. Refactored scanner, parser, and interpreter to include line numbers in error messages (with Ben)
12. Added tests for error messages
13. Fixed corner-case symbol-table bugs
14. Wrote part 4 of the presentation
15. Made the mapper animation for the presentation
16. Wrote the testing section of the report

• Waseem:

1. Assisted with writing proposal
2. Assisted with language design
3. Wrote the Example Code section of the LRM
4. Coded the scanner
5. Assisted with coding the parser
6. Coded the initial “helloworld” interpreter (with Rob)
7. Coded DruL’s built-in functions and methods and added corresponding test cases (with Rob)
8. Coded text file output
9. Wrote part 3 of the presentation
10. Updated the LRM for the report (with Ben)
11. Wrote the tutorial section of the report (with Ben)
12. Added the Divide by zero catch inside DruL.
4.5 Tools and Languages

All of our source code was written using OCaml with the exception of the special syntaxes used by ocamllex and ocamlyacc, and the test-suite driver which was written in Python.

4.5.1 Tools

• **Lexer**: We used ocamllex to compile our ocamllex code into an Ocaml lexer/tokenizer, which given DruL source code, produces a token stream.

• **Parser**: We used ocamlyacc to compile our ocamlyacc code into an Ocaml parser, which given a token stream, produces a DruL abstract-syntax-tree.

• **MIDI Output**: MIDI (Musical Instrument Digital Interface) is a binary music protocol and file format that contains “event messages” for an audio device (e.g. a sound card or synthesizer). MIDI files are playable on many common multimedia players (e.g. Quicktime). DruL does not generate MIDI files directly. Rather it uses midge, which is yet another music composition language that compiles to MIDI. The language is not entirely different from DruL, however it allows for other instruments than drums and thus also has different note pitches and durations. However, midge doesn’t not have contructs for algorithmic compositions comparable to the power of DruL’s. In short, when DruL’s outputMIDI method is called on a clip, the DruL interpreter produces midge code which is then piped to midge to produce the desired MIDI output file.

• **Lilypond**: Lilypond is a typesetting language. DruL can produce Lilypond files. These output files can then be compiled into typeset PDF’s (of sheetmusic) using Lilypond. DruL does not automate this however.

4.5.2 Code Editors

No one on our used the same code editor. None of us used an IDE. Team members used the following editors for all of their code (OCaml, latex, etc.):

• **Rob**: jEdit
• Ben: BBEdit
• Thierry: emacs
• Waseem: gedit

4.5.3 Documentation

All documentation was produced using LaTeX with the exception of the presentation, which was made using Microsoft PowerPoint.

4.5.4 Version Control

We used Google Code and Subversion (SVN) for our source version control and issue tracking.

4.6 Project Log

See the Appendix [3]
Chapter 5

Architectural Design

5.1 Architecture Diagram

![Architecture Diagram]

Figure 5.1: Arrows heads on edges show direction of data-flow.
5.2 Component Interfaces

The DruL interpreter is (as shown above) architecturally very simple.

1. The parser accepts a list of tokens from the scanner and builds a list of DruL
   statements (structured according to DruL’s AST interface) to pass to the main
   unit of the interpreter. These components rely heavily on OCaml’s Lexing and
   Parsing libraries.

2. The interpreter is monolithic: with the exception of the output module, all of
   its major sub-components are built into one set of mutually recursive functions
   (in the file `drul_main.ml`—see appendix C.1.2 on page 94). This monolith takes
   the statement list produced by the parser, evaluates it step by step (performing
   semantic checks on each statement only when program flow arrives at it), and
   passes the resulting structures to the output library when appropriate.

3. The output library is implemented as a set of simple utility functions: each
   takes a single DruL data structure and a small amount of extra data (the exact
   breakdown is unfortunately not well standardized, and varies from output type
   to output type), and returns a string formatted for the appropriate output
   style.

The monolithic design of the interpreter is necessitated by the single-pass approach
taken to interpretation and by the dynamic typing of DruL variables: a re-implementation
that included compilation and checking passes could also maintain cleaner separation
of concerns.

Chapter 6

Test Suite

In the section we present the test suite we built and used for the DruL project. We start in Section 6.1 by showing the basic idea and limits for our testing program. In Section 6.2 we give details about the implementation. Finally, we give samples tests in Section 6.3 and explain what they test.

6.1 Overview

We built two different testing functions in order to debug DruL and help is maintainability: LaunchTestParser and LaunchTest. There usage is very similar.

LaunchTestParser’s goal is to make sure every meaningful DruL code passes through the scanner and parser without errors. We do not make sure that malformed DruL code is intercepted. The program passes a set of DruL code samples to the interpreter, and report whether a message error was produced. This sort of testing was very useful at the beginning of the project, but was later replaced by the more general LaunchTest.

LaunchTest takes a set of DruL code samples, pass them to the interpreter, and compares the output with some predefined output. Therefore, we can test both cases that fail (by catching the error message) or that correctly pass (by printing to the standard output).
6.2 Implementation

We implemented the two above testing programs in Python. This scripting language allows for rapid development and has an excellent packages for handling files. A test file has to have a certain extension (\texttt{.drultest}) and so does the desired output (\texttt{.drultestout}). The core of the testing programs, aside from finding the test files and passing them to the interpreter, is a simple “diff” function. This “diff” tells us if every line of two files are exactly the same or not. Everything is recorded in a LOG, whose name encodes the date and time of the test.

6.3 Sample tests

We present some typical tests for both the parser and the interpreter. In the second case, we also give the desired output.

6.3.1 Tests for DruL Parser

\texttt{/TestSuite/ParserTests/logicalORAND.drultest}
\begin{verbatim}
a = 1; 
b = 2; 
( false || true && false );
( true && false || true );
(a || b && 3 || false && true );
(true || false) && ((false && true || true) || true);
\end{verbatim}

\texttt{/TestSuite/ParserTests/print.drultest}
\begin{verbatim}
print ("1");
print("allo");
print ("yo!374847322937*1-232-./\_\*(\$\#"");
print(pattern(""));
print( pattern ("010111001"));
a = pattern("11110");
print (a);
b = 3;
p

print (a); 
\end{verbatim}
6.3.2 Tests for DruL

/TestSuite/Tests/pattern12.drultest

p11 = map(pattern("1111"))
{

6.4 Conclusion

The tests were designed by every team member, usually following the addition of a feature to DruL interpreter. We tried to keep the tests small and specific in order to better spot bugs. However, we also believe that “the more the better”, thus we cannot say that the test were wisely chosen. Fortunately, there a smart-ass inside of everyone, and we do believe we tested most of the possible flaws.

Our test suite (programs and test files) adds up to 115 cases and about 1100 lines, almost as much as DruL itself. However, we felt it was time well spent for two major reasons:

- We did find bugs early in the coding process thanks to the test suite. One particular example is the precedence for member functions that we had forgotten.
- A complete test suite seems the only way to allow multiple programmers to modify a file without breaking code written by someone else

Thus we believe that a complete test suite is an essential part of a compiler’s project and should be started before the actual language compiler.
Chapter 7

Lessons Learned

7.1 Introduction

In this chapter each team member tells about some lessons he learned from the project, and what he would do differently if we had start all over again.

7.2 Rob (team leader)

Coding standards are important, especially when using a new language that’s unlike anything the team members have seen before. Unfortunately, this is when standards are least likely to be used because no one knows of any relevant standards. Our team attempted to fit the square peg that is OCaml into the round holes that are the C and Java coding standards. This didn’t work very well. In hindsight, we should have spent some time reading about suggested coding conventions for OCaml and researched how to organize a non-trivial OCaml code-base. We spent a long time agonizing over the monolithic spaghetti code that was our intereter before we finally got our heads straight and refactored it. However, we never reached a consensus on the proper way to format (e.g. indent) OCaml. I still find our code very hard to read. Also, domain specific conventions (assuming they exist) for writing a translator would have been useful. For example, it got very confusing trying to keep track which of “int”, “Int”, and “CInt” were an OCaml type, a DruL type, or a DruL AST type. I had to look back to our type definitions almost everytime. In retrospect, prefixes such as “ast_int” and “dru_int” might have been less confusing.
7.3 Ben

I was surprised and impressed with how effective pair programming turned out to be. Leaving aside the technical issues, having second check on “the obvious way to do things” prevented me from getting into several potentially painful situations, when there was a much simpler solution available (this is especially relevant when working with a new language, of course).

Despite the amount of work done with pair programming, we still ran into some forms of communication trouble. In retrospect, a little more discussion up front about standards for code format and design (and for version control use) would have been helpful, at least in theory (it’s hard to have a coding standard for a language that you don’t actually know). Our error messages ended up somewhat inconsistent, and our log messages were sometimes uninformative (especially at first): better up-front coordination could have prevented those problems.

It is tempting to say that a more careful up-front design would have been well-advised, since it would definitely have been helpful—but since we were creating something we didn’t really know how to create, using a language none of us was tremendously familiar with, it is unclear that spending more time on up-front design would actually have been productive in this case. Smaller-scale design issues, on the other hand, would have benefitted from a bit more forethought: we ended up with several somewhat inconsistent APIs for related helper functions, which could easily have been avoided by a little up-front communication or earlier and more aggressive refactoring. We did refactor often to retrofit better design onto the code we had written (made simpler by the easy-to-run regression test suite), but more aggressive refactoring of minor concerns would probably have sped things up toward the end, and would certainly have left us with a more maintainable final product. The type-checking and type-inference features of OCaml make this form of refactoring much safer than it is in many languages, and we should have taken more advantage.

More importantly, from the moment that we had working code, we should have made more active use of Subversion’s branching capabilities, to avoid worries about breaking the main source tree while working on major features. We ended up re-inventing branching at least once, and leaving the entire tree in a non-working state for a couple of evenings, which could readily have been avoided.
7.4 Thierry

One part of the code I especially worked on is the test suite, but I still was surprised to see how important it turned out to be. In a new project, I would either build a more powerful testing program, or spend more time to find an appropriate package online. For instance, our current testing program does not have the ability to test an output file instead of the standard output. It would have become a problem if our language was designed for file operations.

Another lesson learned is the importance of helper functions designed early. At one point, every one of us had design his own method to lookup into the environment, and obviously we multiplied the number of bugs. For some functions, it is so obvious that they were going to be needed that we should have spent the time, as a team, to define them. Their documentation is also an important aspect when you work in a team of more than two programmers.

Following that idea, we probably did not use enough the “issue tracking” on Google code, the platform we used to host our project. Emails does not work as well...

7.5 Waseem

Most important lesson in while coding in OCaml is to modularize the code. Those match with clauses keep getting messier and also there is a lot of code repetition while implementing similar functions or methods on the same language type object, e.g., pattern, clip, etc. Therefore, it is always good to have the helper functions, that can be used later on, in the code. This was my first group project of this level and believe it or not, my first time using version control:); Really makes your life easier. Of course, having those lexer and parser tools do most of the work for you is vry helpful. OCaml in itself is a rather powerful language. Syntax tends to get ’messy’, however, its power is well to be noted. The code tends to be compact, especially when you factor out code that is repeated.

Working in pairs is definitely more helpful than working on one thing alone. In the former case you less likely tend to get stuck at a point, as compared to the later case.

bunch of updates to report

r406  |  benwarfield  |  2008-12-19  04:48:44  -0500  (Fri, 19 Dec 2008)  |  1 line
Added code listings to appendices. Some are kind of wide.
put tutorial section back in

Tweaked colored-code sections.

Stripped useless comments.

Made the end of this file a little less... wide.

Test for divide by zero.

Added isnull method to beat.

division by zero caught inside drul

rand and reverse added in LRM

Lessons added

Promoted a bunch of deserving subsections.

Dumbed quotation marks in code sections back down.

That should be \ref not \label...
Changed all the verbatims to lstlisting. Also fixed the everything-is-red problem. Two things may not be actually connected.

r392 | benwarfield | 2008-12-19 02:36:44 -0500 (Fri, 19 Dec 2008) | 2 lines

Added Tutorial section, and tweaked one footnote in the RefManual out of general puckishness.

added an overview of drul to intro

r387 | robstewart2 | 2008-12-19 01:22:16 -0500 (Fri, 19 Dec 2008) | 1 line

cleaned up ProjectPlan.tex

r386 | robstewart2 | 2008-12-19 00:38:45 -0500 (Fri, 19 Dec 2008) | 1 line

fixed architecture table. added project plan to report.tex

r385 | benwarfield | 2008-12-19 00:37:24 -0500 (Fri, 19 Dec 2008) | 1 line

Fixed up front page a bunch.

r384 | robstewart2 | 2008-12-19 00:24:35 -0500 (Fri, 19 Dec 2008) | 1 line

attempting to fixed latex errors because of _ in Architecture.tex

r383 | robstewart2 | 2008-12-19 00:20:50 -0500 (Fri, 19 Dec 2008) | 1 line

added arch diagram pdf. cleaned up project plan in report

r382 | robstewart2 | 2008-12-19 00:03:37 -0500 (Fri, 19 Dec 2008) | 1 line

added an architecture diagram
mostly finished project plan

Whoops.

Adjustments to formatting (still unable to get the figure onto the cover page, though).

Minor tweak to outputMidi paragraph.

Fixes to code in (remaining) examples.

Fixed a couple of examples, and updated output section.

Typo in the first paragraph. Whoops!

Refmanual errata: return, instrument definition fixes; scoping explained, expressions and string definitions cleaned up.

minor

architectural design section started

clip and instruments in RefMan seems OK

test sutie chapter updated
tbm lessons learned is done

report has table of content

general layout of lessons learned chapter

test suite section kinda done... need approval by someone else

added empty Project Plan

changed intro section to chapter

Use "report" format, which includes chapters; use chapters.

added intro to report

Fixed cover page.

going longer

using colors
test suite added

beginning of the report

cleaned up presentation

added thierry’s slides to parts 1-2

added waseems slides to parts 1-2

lines of code added

updated list of reserved keywords

we catch bad mapper naming

we catch bad mapper naming

instr def in mappers solved

can’t assing instruments inside mappers

important test for weird assignments of mapper that should fail
Changed keyword check message (and keyword check).

r344 | benwarfield | 2008-12-18 14:23:01 -0500 (Thu, 18 Dec 2008) | 1 line

Changed keyword check message (and keyword check).

r343 | benwarfield | 2008-12-18 13:49:48 -0500 (Thu, 18 Dec 2008) | 1 line

Trapped an un-trapped internal error (mapper/variable name collision).

r285 | benwarfield | 2008-12-17 02:17:42 -0500 (Wed, 17 Dec 2008) | 1 line

Made error messages look like they were written by a human being, and updated related tests.

---

r284 | benwarfield | 2008-12-16 22:10:18 -0500 (Tue, 16 Dec 2008) | 1 line

Made interpreter take a command-line argument as a filename for input if one is provided.
Added line numbers to output–related exceptions.

Removed spurious comments.

Got line numbers passed down to "clip" and to mapper–related helpers.

Fixes to fixes on exception–raising.

make_clip now takes a line number

errors fixed

failures should not have line number or -1, others errors do

Added line numbers to a lot of exceptions.

failures should now have line number or -1

some errors updated with line number

some errors updated with line number

exceptions takes also an int
Made all uses of expr into tagged_expr. Things somehow still all work.

Reduced indentation a bit in output function.

Added line-number tagging to scanner and parser and AST.

Corrected the file permission problem for output to file

in parser, tokens take at least one int, the line number, this upload BREAKS EVERYTHING
but we're fixing it

Corrected header of drul_types.ml

Minor cleanup in interpreter.

Rearranged code into multiple files, for ease of maintenance.

Comments Added at places.

better error when assigning a clip without defining instruments

clip assignment solved
partly solve the problem of assignments, but we can still assign to clip...

assign to pattern, fails for the moment

makes sure we can't assign anything to true or false

test assignment to 'rand', fails for the moment

test updated, no problem with instruments, can't assign it

instruments assignment test, fails for the moment

clip assignment test, fails for the moment

Removed .txt check. File name can be anything the user wants it to be, as far as we are concerned.

Just added file name check. I think as far as Linux is concerned we do not need file name checks. But it looks better for a text file to have .txt extension.

output.txt file functions now output clips to the files, just like print does on the stdout. (I will look into the issue of outputting clips in mapper.)

output.txtfile_*** functions do what print does except it doesn't output clips yet. The two extensions are append and truncate to choose what the user wants to do with the already existing file.
output test updated

output.txt_truncate and output.txtfile_append do as their names suggest.

I think output.txtfile() needs to give a valid filename along with the string.

output.txtfile() outputs a string to the file with extension .txt, if the
dle already exists, it truncates it and if it doesn’t then it creates it.

Need to flush the out_channel and close it.

The check for file extension added (I don’t know if we need it for Linux, but
windowcs cares about extensions). output.txtfile(...) should only care about .txt files.

Made clips exist, and print.

Commented out useless extra prints.

Added a new token OUTPUT. Changed ast, scanner and parser to accomodate for
output.txtfile format. Haven’t yet finished with the output function yet.
For now it only creates/opens a file to write to it.

Squashed shift–reduce issues with left–arrow.

we can create empty clips of given size

Refactored method calls to use eval.arg.list (and fixed a typo).
Refactored function calls to use eval_arg_list.

added InstrAssign expressions back in

now instruments() call the default instruments

changed InstrAssign to InstrDef

added Ben’s gcd example to the test suite

minor modification to instrument_pos functions, better exception catching

function get_instrument_pos works, damn you ocaml syntax that made us lose an hour on this

major change for instruments, now an assignment to handle env, passes basics tests

3 basic tests for instruments
Created examples directory, with working GCD in it.

---

instrument definition is done. clip is in progress and commented out

---

more info on the type of whitespace encountered in debug mode

checks if we try to assign Beat or PatternAlias, and say something stupid about it

### r201
| thierrybm@hotmail.com | 2008-12-03 15:23:49 -0500 (Wed, 03 Dec 2008) | 1 line |
Quashed warning in test.ml.

Slice method updated.

Some Tests edited for errors

Not Much

Spelling Corrections in the Header Comments

more comments

specific exception created for illegal assignment

check at runtime for assignment of string and boolean

concat tests

concat tests
Dynamic scoping, and minor modifications to make beats work.

Made "return" work, and tested it.

Noted scope stuff.

Whitespace and comment changes.

more tests fixed

syntax of some tests updated, solved most of parser errors

one test corrected

One simple test for map expression.

Finished fixes relating to map scope entry, including finally figuring out how to create the symbol table type we wanted in the first place. Integrated changes back
into main interpreter codebase and deleted branch file.

-- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- --

r176 | robstewart2 | 2008−11−24 18:20:19 −0500 (Mon, 24 Nov 2008) | 1 line

added concat and slice to the interpreter

-- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- --

r175 | thierrybm@hotmail.com | 2008−11−24 18:01:05 −0500 (Mon, 24 Nov 2008) | 1 line

Ben, this is for you, I cannot fix the eval_arg_list, I’ve created two dummy functions, still doesn’t compile.... but we’re almost there

-- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- --

r174 | thierrybm@hotmail.com | 2008−11−24 17:46:49 −0500 (Mon, 24 Nov 2008) | 1 line

map may be solved, see function eval_arg_list, but still does not compile

-- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- --

r173 | benwarfield | 2008−11−24 17:23:54 −0500 (Mon, 24 Nov 2008) | 1 line

BROKEN but Thierry will fix it—further work toward mapCall expression evaluation.

-- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- --

r172 | waseemilahi | 2008−11−20 22:10:55 −0500 (Thu, 20 Nov 2008) | 1 line

Repeat with argument value < 1 now raises exception for invalid argument

-- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- --

added repeat method handling to interpreter

-- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- --

r166 | thierrybm@hotmail.com | 2008−11−20 18:18:26 −0500 (Thu, 20 Nov 2008) | 1 line

method call now is left associative

-- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- -- --

r165 | benwarfield | 2008−11−20 18:00:40 −0500 (Thu, 20 Nov 2008) | 1 line

78
Upgraded patterns, and added mapper creation.

solved shiftreduce conflict on mcall by adding right additivity

more future tests

Broke function calls out into their own function, and added a trap for invalid ones.

Added Basic Patterns

removeing useless file
minor changes

Fixed string-escape bug--test now passes!

Variable assignment!!!

Added if/elseif/else to interpreter.

all tests pass, pretty good parser

Interpreter now supports all binary and unary operations (tests included).

small updates

update test

update test

one more test

the interpreter can evaluate int arithmetic and print it
better random

one more test

better parser, everything except if else ... seems to work

added stupid stuff :)

Added environment to execution routines as (stringmap, parent) pair.

a.b() and a.b(a) cases are parsed

a.b case is parsed, now need to work or decide on a.b()

better working LaunchTests, handle stdout and stderr, stderr assumed always at the end

makefile now creates interpreter by default

Added printing of numbers and booleans, added those to the printing test, added a failing test for " and \", and updated svn:ignore to ignore logs.

more real tests like hello world

Turned off scanner debugging.
Launching test updated to reach program interpret

new parser tests

new parser tests

new parser tests

new parser tests

new parser tests

new parser tests, correct the previous wrong extensions

new parser tests

new parser tests

new parser tests

new parser tests

new parser tests

inter bipolar works for printing

inter bipolar still doesn’t work...

inter bipolar still doesn’t work...

Added tests from parser development side (three pass, one fails).
r116 | benwarfield | 2008−11−12 17:38:52 −0500 (Wed, 12 Nov 2008) | 1 line
Escape for paths with spaces (actually by Thierry, but on my computer).

</table>

remove useless file

to test the parser, use with ./testing

added the interpreter. not done. haven’t even compiled it

Fixed a bug resulting from change from left-recursion to right-recursion in expr.list rule.

Added ugly-printer for very simple syntax trees.

test suite ready

better testing function

Added eol-style property to a couple files.

Resolved expr.list problem by making it comma-separated, and added errata file to RefManual folder to note such changes.

Made escaping a backslash in a string constant work.

Example code from refmanual used for debugging
Added "map" expressions to parser, and modified AST slightly to reflect the fact that we do not have the parameter information for a mapper available in the parser.

Made "block" reverse its statement list, so if/else/mapper need not do it.

Added support for "else", and discovered several shift-reduce conflicts in the grammar as currently specified.

Added a level of indirection for statement lists (woohoo!), and added assignment and mapper definition statements, as well as if-block, to statement definition. No handling of "else" token yet.

Added testing program to actually parse input and see if it contains valid DruL code. Many modifications to scanner to make this fly, plus adding string and boolean constants to the AST and the parser, and making the base case for the parser (empty program) work.

adding folders for test suite

Squished warning in scanner.

Reapplied accidentally backed-out bugfixes.

kept my changes, not bens

Added Makefile with appropriate dependencies to build everything as far as it is so far possible to build it.
Added import of Parser module, and fixed identifier—too—long error message.

Moved AST and Scanner to Parser directory, and fixed a couple of bugs in the Parser, which now compiles all the way to an object file.

Fixed syntax error and added support for statements and for calling functions of one parameter. Like "print". Hypothetically speaking.

Operator precedence and simple expressions added to parser.

Removed blank lines and detabbed.

Fixed line—ending issues on parser/scanner.

Fixed problem with circular dependency in definitions of stmt/expr/mapper.

Fixed a couple more minor issues, but not the big one.

Fixed some, but not all, of the circularity problems in our AST definition.

Line—endings, tab expansion, and name consistency (arithOp/intOp).

Minor change towards getting practical scanner for DruL

Improvements to AST.
dummy parser introduced. need tokens to work in the scanner.

identifier is less than equal to 64 in length. Also eof termination added.

some changes done to scanner. Still working on the basics.

null removed in scanner

Trivial usage change.

date fixed

more on output.txt file

one textit removed

empty pattern returned

Reformatted example code.

typo in date fixed
date fixed

Tweaked comment definition.

just to be sure

Parenthesized example print statements, and removed newline characters.

one line added to the print subsection

() added

better output

Added $vars to Identifiers section, and changed reference from Mapper section to Map section (since that section is more relevant).

null and more on $

null and more on $

better indentation

slice added
Added "beat" concept, and removed terminal semicolon from mapper definition.

Resolved a bunch of declare/define confusion.

Checking in various changes on behalf of Rob (whitespace and edits, largely).

$ added in the example

small typos and $ sign in anonymous mappers

Made a folder for AST.

I did add semicolons at the end of each mapper definition. They are statements and statements end with a semicolon.

Semicolons added at the end of where anonymous mapper is used, because those are definitely assignment statements.

Typographic cleanup, and minor textual revision, for beginning of example code.

Spruced up expression/statement section.

Example Code Added. Some of the explanation in example section moved to the appropriate earlier sections
namespacer per type

Spruced up expressions and statements a bit (boolean values).

Closed scope for mappers, single namespace for identifiers.

Rather rough draft of statement/expression/block section.
