

An Introduction to Objective Caml

Stephen A. Edwards

Columbia University

Fall 2008

Objective Caml in One Slide

Apply a function to each list element; save the results in a list

```
# let rec map f = function
  [] -> []
  | head :: tail ->
    let r = f head in
    r :: map f tail;;
val map : ('a -> 'b) -> 'a list -> 'b list
# map (function x -> x + 3) [1;5;9];;
- : int list = [4; 8; 12]
```

“Is recursive”

Case splitting

Local name declaration

List support

Recursion

Anonymous functions

Passing a function

Pattern Matching

Polymorphic Types inferred

What Features Does Objective Caml Have?

- ▶ **Lots of Libraries**

All sorts of data structures, I/O, OS interfaces, graphics, support for compilers, etc.

- ▶ **A C-language Interface**

It is easy to call C functions from OCaml and vice versa. Many C libraries already have wrappers.

- ▶ **A Variety of Execution Modes**

Three choices: interactive command-line, bytecode interpreter, and compilation to native machine code.

- ▶ **Lots of Support**

Many websites, free online books and tutorials, code samples, etc.

Why Use Objective Caml?

- ▶ **It's Great for Compilers**

I've written compilers in C++, Python, Java, and OCaml, and it's much easier in OCaml.

- ▶ **It's Succinct**

Would you prefer to write 10 000 lines of code or 5 000?

- ▶ **Its Type System Catches Many Bugs**

It catches missing cases, data structure misuse, certain off-by-one errors, etc. Automatic garbage collection and lack of null pointers makes it safer than Java.

- ▶ **A Better Way to Think**

It encourages discipline and mathematical thinking.

Part I

The Basics

Comments

Objective Caml

```
(* This is a multiline  
comment in OCaml *)  
  
(* Comments  
  (* like these *)  
  do nest  
*)  
  
(* OCaml has no *)  
(* single-line comments *)
```

C/C++/Java

```
/* This is a multiline  
comment in C */  
  
/* C comments  
   /* do not  
   nest  
*/  
  
// C++/Java also has  
// single-line comments
```

Functions

Objective Caml

```
let ftoc(temp) =  
  (temp -. 32.0) /. 1.8;;  
  
ftoc(98.6);; (* returns 37 *)  
  
ftoc 73.4;; (* returns 23 *)
```

C/C++/Java

```
double ftoc(double temp)  
{  
    return (temp - 32) / 1.8;  
}  
  
ftoc(98.6); /* returns 37 */
```

- ▶ Parentheses around arguments optional
- ▶ No explicit `return`
- ▶ Explicit floating-point operators `-.` and `/.`
- ▶ No automatic promotions (e.g., `int` → `double`)
- ▶ No explicit types; they are inferred
- ▶ `;;` terminates phrases

Programs

Consist of three types of declarations:

```
(* let: value and function declaration *)
let rec fact n = if n < 2 then 1 else n * fact(n - 1);;

(* type declaration *)
type expr = Lit of int | Binop of expr * op * expr;; 

(* exception declaration *)
exception Error of string * location;;
```

Values and types always begin lowercase (e.g., foo, fooBar)

Exceptions always begin uppercase (e.g., MyExcep)

Using OCaml Interactively

```
$ ocaml
  Objective Caml version 3.10.0

# let ftoc(temp) = (temp - 32) / 1.8;;
This expression has type float but is here used with type int

# let ftoc(temp) = (temp -. 32.0) /. 1.8;;
val ftoc : float -> float = <fun>

# ftoc 98.6;;
- : float = 36.999999999999929

# #quit;;
$
```

Double semicolons `;;` terminate phrases (expressions, declarations).

Single semicolons `;` indicate sequencing.

Recursion

Objective Caml

```
let rec gcd(a, b) =  
  if a = b then  
    a  
  else if a > b then  
    gcd(a - b, b)  
  else  
    gcd(a, b - a)
```

C/C++/Java

```
int gcd(int a, int b)  
{  
  while (a != b) {  
    if (a > b)  
      a -= b;  
    else  
      b -= a;  
  }  
  return a;  
}
```

- ▶ Recursion can be used to replace a loop.
- ▶ Tail recursion runs efficiently in OCaml.
- ▶ Function calls: *func arg1 arg2 ...*
- ▶ *if-then-else* is an expression, as is everything.
- ▶ *let rec* allows for recursion

Basic Types

```
let i = 42 + 17;;          (* int *)
print_int i;;

let f = 42.0 +. 18.3;;      (* float *)
print_float f;;

let g = i + f ;;          (* ERROR *)
let g = (float_of_int i) +. f;; (* OK *)

let b = true or false;;    (* bool *)
print_endline (if b then "true" else "false");;

let c = 'a';;              (* char *)
print_char c;;

let s = "Hello " ^ "World!";; (* string *)
print_endline s;; 

let u = ();;                (* unit, like "void" in C *)
```

Standard Operators and Functions

+ - * / mod	Integer arithmetic
+. -. *. /. **	Floating-point arithmetic
ceil floor sqrt exp	
log log10 cos sin	Floating-point functions
tan acos asin atan	
not &&	Boolean operators
= <>	Structual comparison (polymorphic)
== !=	Physical comparison (polymorphic)
< > <= >=	Comparisons (polymorphic)

Structural vs. Physical Equality

Structural equality (=) compares values; physical equality (==) compares pointers. Compare strings and floating-point numbers structurally.

```
# 1 = 3;;
- : bool = false
# 1 == 3;;
- : bool = false
# 1 = 1;;
- : bool = true
# 1 == 1;;
- : bool = true

# 1.5 = 1.5;;
- : bool = true
# 1.5 == 1.5;;
- : bool = false      (* Huh? *)
# let f = 1.5 in f == f;;
- : bool = true
```

```
# "a" = "a";;
- : bool = true
# "a" == "a";;
- : bool = false    (* Huh? *)
# let a = "hello" in a = a;;
- : bool = true
# let a = "hello" in a == a;;
- : bool = true
```

Tuples

Pairs or tuples of different types separated by commas.

Very useful lightweight data type, e.g., for function arguments.

```
# (42, "Arthur");;
- : int * string = (42, "Arthur")
# (42, "Arthur", "Dent");;
- : int * string * string = (42, "Arthur", "Dent")

# let p = (42, "Arthur");;
val p : int * string = (42, "Arthur")
# fst p;;
- : int = 42
# snd p;;
- : string = "Arthur"

# let trip = ("Douglas", 42, "Adams");;
val trip : string * int * string = ("Douglas", 42, "Adams")
# let (fname, _, lname) = trip in (lname, fname);;
- : string * string = ("Adams", "Douglas")
```

Lists

```
(* Literals *)
[];;          (* The empty list *)
[1];;         (* A singleton list *)
[42; 16];;    (* A list of two integers *)

(* cons: Put something at the beginning *)
7 :: [5; 3];;  (* Gives [7; 5; 3] *)
[1; 2] :: [3; 4];; (* BAD: type error *)

(* concat: Append a list to the end of another *)
[1; 2] @ [3; 4];;  (* Gives [1; 2; 3; 4] *)

(* Extract first entry and remainder of a list *)
List.hd [42; 17; 28];; (* = 42 *)
List.tl [42; 17; 28];; (* = [17; 28] *)
```

- ▶ The elements of a list must all be the same type.
- ▶ `::` is very fast; `@` is slower— $O(n)$
- ▶ Pattern: create a list with `cons`, then use `List.rev`.

If-then-else

if $expr_1$ **then** $expr_2$ **else** $expr_3$

If-then-else in OCaml is an expression. The *else* part is compulsory, $expr_1$ must be Boolean, and the types of $expr_2$ and $expr_3$ must match.

```
# if 3 = 4 then 42 else 17;;
- : int = 17
```

```
# if "a" = "a" then 42 else 17;;
- : int = 42
```

```
# if true then 42 else "17";;
```

This expression has type string but is here used with type int

Global and Local Value Declarations

Local: bind *name* to *expr₁* in *expr₂* only.

The most common construct in OCaml code.

let *name* = *expr₁* **in** *expr₂* ;;

Global: bind *name* to *expr* in everything that follows;

let *name* = *expr* ;;

```
# let x = 38 in x + 4;;
- : int = 42
# x + 4;;
Unbound value x

# let x = 38;;
val x : int = 38
# x + 4;;
- : int = 42
```

Local Value Declaration vs. Assignment

Local value declaration can be used to bind a succession of values to a name, but this is not assignment because the value disappears in the end.

```
# let a = 4 in
  let a = a + 2 in
  let a = a * 2 in
  print_int a;;
12- : unit = ()

# a;;
Unbound value a
```

This looks like sequencing, but it is really data dependence.

Functions

A function is just another type whose value can be defined with an expression.

```
# fun x -> x * x;;
- : int -> int = <fun>
# (fun x -> x * x) 5;; (* function application *)
- : int = 25

# fun x -> (fun y -> x * y);;
- : int -> int -> int = <fun>
# fun x y -> x * y;; (* shorthand *)
- : int -> int -> int = <fun>
# (fun x -> (fun y -> (x+1) * y)) 3 5;;
- : int = 20

# let square = fun x -> x * x;;
val square : int -> int = <fun>
# square 5;;
- : int = 25
# let square x = x * x;; (* shorthand *)
val square : int -> int = <fun>
# square 6;;
- : int = 36
```

Static Scoping

Another reason *let* is not assignment: OCaml picks up the values in effect where the function (or expression) is defined. Global declarations are not like C's global variables.

```
# let a = 5;;
val a : int = 5

# let adda x = x + a;;
val adda : int -> int = <fun>

# let a = 10;;
val a : int = 10

# adda 0;;
- : int = 5          (* adda sees a = 5 *)

# let adda x = x + a;;
val adda : int -> int = <fun>

# adda 0;;
- : int = 10         (* adda sees a = 10 *)
```

Recursive Functions

By default, a name is not visible in its defining expression.

```
# let fac n = if n < 2 then 1 else n * fac (n-1);;
Unbound value fac
```

The *rec* keyword makes the name visible.

```
# let rec fac n = if n < 2 then 1 else n * fac (n-1);;
val fac : int -> int = <fun>
# fac 5;;
- : int = 120
```

The *and* keyword allows for mutual recursion.

```
# let rec fac n = if n < 2 then 1 else n * fac1 n
  and fac1 n = fac (n - 1);;
val fac : int -> int = <fun>
val fac1 : int -> int = <fun>
# fac 5;;
- : int = 120
```

Some Useful List Functions

Three great replacements for loops:

- ▶ **List.map f [a1; ... ;an] = [f a1; ... ; f an]**
Apply a function to each element of a list to produce another list.
- ▶ **List.fold_left f a [b1; ...;bn] =
f (...(f (f a b1) b2)...) bn**
Apply a function to a partial result and an element of the list to produce the next partial result.
- ▶ **List.iter f [a1; ...;an] =
begin f a1; ... ; f an; () end**
Apply a function to each element of a list; produce a unit result.
- ▶ **List.rev [a1; ...; an] = [an; ... ;a1]**
Reverse the order of the elements of a list.

List Functions Illustrated

```
# List.map (fun a -> a + 10) [42; 17; 128];;
- : int list = [52; 27; 138]

# List.map string_of_int [42; 17; 128];;
- : string list = ["42"; "17"; "128"]

# List.fold_left (fun s e -> s + e) 0 [42; 17; 128];;
- : int = 187

# List.iter print_int [42; 17; 128];;
4217128- : unit = ()

# List.iter (fun n -> print_int n; print_newline ())
[42; 17; 128];;
42
17
128
- : unit = ()
# List.iter print_endline (List.map string_of_int [42; 17; 128]);;
42
17
128
- : unit = ()
```

Example: Enumerating List Elements

To transform a list and pass information between elements, use *List.fold_left* with a tuple:

```
# let (l, _) = List.fold_left
  (fun (l, n) e -> ((e, n)::l, n+1)) ([] , 0) [42; 17; 128]
  in List.rev l;;
- : (int * int) list = [(42, 0); (17, 1); (128, 2)]
```

Result accumulated in the (l, n) tuple, *List.rev* reverses the result (built backwards) in the end. Can do the same with a recursive function, but *List.fold_left* separates list traversal from modification:

```
# let rec enum (l, n) = function
  []    -> List.rev l
  | e::tl -> enum ((e, n)::l, n+1) tl
  in
  enum ([] , 0) [42; 17; 128];;
- : (int * int) list = [(42, 0); (17, 1); (128, 2)]
```

Pattern Matching

A powerful variety of multi-way branch that is adept at picking apart data structures. Unlike anything in C/C++/Java.

```
# let xor p = match p
  with (false, false) -> false
    | (false, true) -> true
    | (true, false) -> true
    | (true, true) -> false;;
val xor : bool * bool -> bool = <fun>
# xor (true, true);;
- : bool = false
```

A name in a pattern matches anything and is bound when the pattern matches. Each may appear only once per pattern.

```
# let xor p = match p
  with (false, x) -> x
    | (true, x) -> not x;;
val xor : bool * bool -> bool = <fun>
# xor (true, true);;
- : bool = false
```

Case Coverage

The compiler warns you when you miss a case or when one is redundant (they are tested in order):

```
# let xor p = match p
  with (false, x) -> x
    | (x, true) -> not x;;
```

Warning P: this pattern-matching is not exhaustive.

Here is an example of a value that is not matched:

(true, false)

```
val xor : bool * bool -> bool = <fun>
```

```
# let xor p = match p
  with (false, x) -> x
    | (true, x) -> not x
    | (false, false) -> false;;
```

Warning U: this match case is unused.

```
val xor : bool * bool -> bool = <fun>
```

Wildcards

Underscore (`_`) is a wildcard that will match anything, useful as a default or when you just don't care.

```
# let xor p = match p
  with (true, false) | (false, true) -> true
    | _ -> false;;
val xor : bool * bool -> bool = <fun>
# xor (true, true);;
- : bool = false
# xor (false, false);;
- : bool = false
# xor (true, false);;
- : bool = true

# let logand p = match p
  with (false, _) -> false
    | (true, x) -> x;;
val logand : bool * bool -> bool = <fun>
# logand (true, false);;
- : bool = false
# logand (true, true);;
- : bool = true
```

Pattern Matching with Lists

```
# let length = function (* let length = fun p -> match p with *)
    [] -> "empty"
  | [_] -> "singleton"
  | [_;_] -> "pair"
  | [_;_;_] -> "triplet"
  | hd :: tl -> "many";;
val length : 'a list -> string = <fun>

# length [];;
- : string = "empty"

# length [1; 2];;
- : string = "pair"

# length ["foo"; "bar"; "baz"];;
- : string = "triplet"

# length [1; 2; 3; 4];;
- : string = "many"
```

Part II

Some Examples

Application: Length of a list

```
let rec length l =
  if l = [] then 0 else 1 + length (List.tl l);;
```

Correct, but not very elegant. With pattern matching,

```
let rec length = function
  []      -> 0
  | _ :: t1 -> 1 + length t1;;
```

Elegant, but inefficient because it is not tail-recursive (needs $O(n)$ stack space). Common trick: use an argument as an accumulator.

```
let length l =
  let rec helper len = function
    []      -> len
    | _ :: t1 -> helper (len + 1) t1
  in helper 0 l
```

This is the code for the List.length standard library function.

OCaml Can Compile This Efficiently

OCaml source code

```
let length list =
  let rec helper len = function
    []      -> len
    _ :: t1 -> helper (len + 1) t1
  in helper 0 list
```

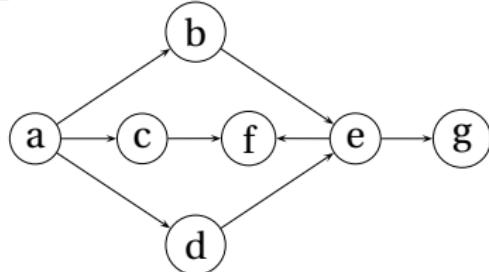

- ▶ Arguments in registers
- ▶ Pattern matching reduced to a conditional branch
- ▶ Tail recursion implemented with jumps
- ▶ LSB of an integer always 1

ocamlopt generates this x86 assembly

```
camlLength_helper:
.L101:
  cmpl  $1, %ebx          # empty?
  je    .L100
  movl  4(%ebx), %ebx # get tail
  addl  $2, %eax         # len++
  jmp   .L101
.L100:
  ret

camlLength_length:
  movl  %eax, %ebx
  movl  $camlLength_2, %eax
  movl  $1, %eax          # len = 0
  jmp   camlLength_helper
```

Application: Directed Graphs

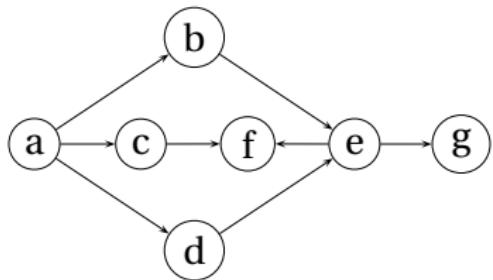

```
let edges = [
  ("a", "b"); ("a", "c");
  ("a", "d"); ("b", "e");
  ("c", "f"); ("d", "e");
  ("e", "f"); ("e", "g") ];;
```

```
let rec successors = function
  (_, [])           -> []
| (n, (s, t) :: edges) ->
  if s = n then
    t :: successors(n, edges)
  else
    successors(n, edges);;
```

```
# successors("a", edges);
- : string list = ["b"; "c"; "d"]

# successors("b", edges);
- : string list = ["e"]
```

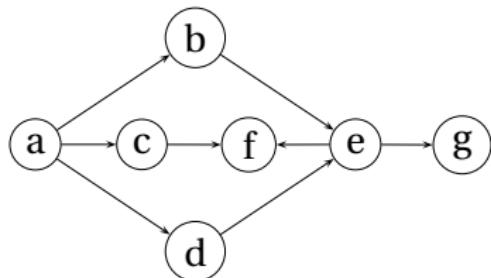

Depth-First Search

```
let rec dfs = function
  ([],      _,      visited) -> List.rev visited
  | (n::nodes, edges, visited) ->
    if List.mem n visited then
      dfs(nodes,           edges,      visited)
    else
      dfs(successors(n, edges) @ nodes, edges, n::visited);;
```

```
# dfs(["a"], edges, []);;
- : string list = ["a"; "b"; "e"; "f"; "g"; "c"; "d"]
# dfs(["e"], edges, []);;
- : string list = ["e"; "f"; "g"]
# dfs(["d"], edges, []);;
- : string list = ["d"; "e"; "f"; "g"]
```

Topological Sort

Remember the visitor at the end.

```
let rec tsort = function
  ([] , _ , visited) -> visited
| (n :: nodes , edges , visited) ->
  tsort(nodes , edges ,
        if List.mem n visited then visited
        else n :: tsort(successors(n , edges) , edges , visited));;
```

```
# tsort(["a"] , edges , []);
- : string list = ["a"; "d"; "c"; "b"; "e"; "g"; "f"]

# let cycle = [ ("a" , "b"); ("b" , "c"); ("c" , "a") ];;
val cycle : (string * string) list = [("a", "b"); ...]
# tsort(["a"] , cycle , []);
Stack overflow during evaluation (looping recursion?).
```

Better Topological Sort

```
exception Cyclic of string;;\n\nlet tsort(seed, edges) =\n  let rec sort = function\n    ([] , _ , visited) -> visited\n    | (n :: nodes, path, visited) ->\n        if List.mem n path then raise (Cyclic n) else\n            sort(nodes, path,\n                  if List.mem n visited then visited else\n                      n :: sort(successors(n, edges), n :: path, visited))\n  in\n  sort([seed], [], []);;
```

```
# tsort("a", edges);;\n- : string list = ["a"; "d"; "c"; "b"; "e"; "g"; "f"]\n\n# tsort("d", edges);;\n- : string list = ["d"; "e"; "g"; "f"]\n\n# tsort("a", cycle);;\nException: Cyclic "a".
```

Part III

More Advanced Stuff

Type Declarations

A new type name is defined globally. Unlike *let*, *type* is recursive by default, so the name being defined may appear in the *typedef*.

```
type name = typedef ; ;
```

Mutually-recursive types can be defined with *and*.

```
type name1 = typedef1  
and   name2 = typedef2  
        :  
and   namen = typedefn ; ;
```

Records

OCaml supports records much like C's *structs*.

```
# type base = { x : int; y : int; name : string };;
type base = { x : int; y : int; name : string; }

# let b0 = { x = 0; y = 0; name = "home" };;
val b0 : base = {x = 0; y = 0; name = "home"}
# let b1 = { b0 with x = 90; name = "first" };;
val b1 : base = {x = 90; y = 0; name = "first"}
# let b2 = { b1 with y = 90; name = "second" };;
val b2 : base = {x = 90; y = 90; name = "second"}

# b0.name;;
- : string = "home"

# let dist b1 b2 =
    let hyp x y = sqrt (float_of_int (x*x + y*y)) in
    hyp (b1.x - b2.x) (b1.y - b2.y);;
val dist : base -> base -> float = <fun>

# dist b0 b1;;
- : float = 90.
# dist b0 b2;;
- : float = 127.279220613578559
```

Tagged Unions/Sum Types

Vaguely like C's *unions*, *enums*, or a class hierarchy: objects that can be one of a set of types. In compilers, great for trees and instructions.

```
# type seasons = Winter | Spring | Summer | Fall;;
type seasons = Winter | Spring | Summer | Fall

# let weather = function
  Winter -> "Too Cold"
  | Spring -> "Too Wet"
  | Summer -> "Too Hot"
  | Fall -> "Too Short";;
val weather : seasons -> string = <fun>

# weather Spring;;
- : string = "Too Wet"

# let year = [Winter; Spring; Summer; Fall] in
  List.map weather year;;
- : string list = ["Too Cold"; "Too Wet"; "Too Hot"; "Too Short"]
```

Simple Syntax Trees and an Interpreter

```
# type expr =
    Lit of int
  | Plus of expr * expr
  | Minus of expr * expr
  | Times of expr * expr;;
type expr =
    Lit of int
  | Plus of expr * expr
  | Minus of expr * expr
  | Times of expr * expr

# let rec eval = function
    Lit(x) -> x
  | Plus(e1, e2) -> (eval e1) + (eval e2)
  | Minus(e1, e2) -> (eval e1) - (eval e2)
  | Times(e1, e2) -> (eval e1) * (eval e2);;
val eval : expr -> int = <fun>

# eval (Lit(42));;
- : int = 42
# eval (Plus(Lit(17), Lit(25)));;
- : int = 42
# eval (Plus(Times(Lit(3), Lit(2)), Lit(1)));;
- : int = 7
```

Tagged Union Rules

Each tag name must begin with a capital letter

```
# let bad1 = left l right;;  
Syntax error
```

Tag names must be globally unique (required for type inference)

```
# type weekend = Sat | Sun;;  
type weekend = Sat | Sun  
# type days = Sun | Mon | Tue;;  
type days = Sun | Mon | Tue  
# function Sat -> "sat" | Sun -> "sun";;  
This pattern matches values of type days  
but is here used to match values of type weekend
```

Tagged Unions and Pattern Matching

The compiler warns about missing cases:

```
# type expr =
    Lit of int
  | Plus of expr * expr
  | Minus of expr * expr
  | Times of expr * expr;;
type expr =
    Lit of int
  | Plus of expr * expr
  | Minus of expr * expr
  | Times of expr * expr

# let rec eval = function
    Lit(x) -> x
  | Plus(e1, e2) -> (eval e1) + (eval e2)
  | Minus(e1, e2) -> (eval e1) - (eval e2);;
Warning P: this pattern-matching is not exhaustive.
Here is an example of a value that is not matched:
Times (_, _)
val eval : expr -> int = <fun>
```

The *Option* Tagged Union: A Safe Null Pointer

Part of the always-loaded core library:

```
type 'a option = None | Some of 'a
```

This is a polymorphic tagged union type: '*a* is any type. *None* is like a null pointer; *Some* is a non-null pointer. The compiler requires *None* to be handled explicitly.

```
# let rec sum = function
  [] -> 0                                     (* base case *)
  | None::tl -> sum tl           (* handle the "null pointer" case *)
  | Some(x)::tl -> x + sum tl;;          (* normal case *)
val sum : int option list -> int = <fun>

# sum [None; Some(5); None; Some(37)];;
- : int = 42
```

Tagged Unions vs. Classes and Enums

	Tagged Unions	Classes	Enums
Choice of Types	fixed	extensible	fixed
Operations	extensible	fixed	extensible
Fields	ordered	named	none
Hidden fields	none	supported	none
Recursive	yes	yes	no
Inheritance	none	supported	none
Case splitting	simple	costly	simple

A tagged union is best when the set of types rarely change but you often want to add additional functions. Classes are good in exactly the opposite case.

Exceptions

```
# 5 / 0;;
Exception: Division_by_zero.

# try
  5 / 0
with Division_by_zero -> 42;;
- : int = 42

# exception My_exception;;
exception My_exception
# try
  if true then
    raise My_exception
  else 0
with My_exception -> 42;;
- : int = 42
```

Exceptions

```
# exception Foo of string;;
exception Foo of string
# exception Bar of int * string;;
exception Bar of int * string

# let ex b =
try
  if b then
    raise (Foo("hello"))
  else
    raise (Bar(42, " answer"))
with Foo(s) -> "Foo: " ^ s
| Bar(n, s) -> "Bar: " ^ string_of_int n ^ s;;
val ex : bool -> unit = <fun>

# ex true;;
- : string = "Foo: hello"
# ex false;;
- : string = "Bar: 42 answer"
```

Maps

Balanced trees for implementing dictionaries. Ask for a map with a specific kind of key; values are polymorphic.

```
# module StringMap = Map.Make(struct
    type t = string
    let compare x y = Pervasives.compare x y
  end);;
module StringMap :
sig
  type key = string
  type +'a t
  val empty : 'a t
  val is_empty : 'a t -> bool
  val add : key -> 'a -> 'a t -> 'a t
  val find : key -> 'a t -> 'a
  val remove : key -> 'a t -> 'a t
  val mem : key -> 'a t -> bool
  val iter : (key -> 'a -> unit) -> 'a t -> unit
  val map : ('a -> 'b) -> 'a t -> 'b t
  val mapi : (key -> 'a -> 'b) -> 'a t -> 'b t
  val fold : (key -> 'a -> 'b -> 'b) -> 'a t -> 'b -> 'b
  val compare : ('a -> 'a -> int) -> 'a t -> 'a t -> int
  val equal : ('a -> 'a -> bool) -> 'a t -> 'a t -> bool
end
```

Maps

```
# let mymap = StringMap.empty;;          (* Create empty map *)
val mymap : 'a StringMap.t = <abstr>

# let mymap = StringMap.add "Douglas" 42 mymap;; (* Add pair *)
val mymap : int StringMap.t = <abstr>

# StringMap.mem "foo" mymap;;           (* Is "foo" there? *)
- : bool = false
# StringMap.mem "Douglas" mymap;;       (* Is "Douglas" there? *)
- : bool = true

# StringMap.find "Douglas" mymap;;      (* Get value *)
- : int = 42

# let mymap = StringMap.add "Adams" 17 mymap;;
val mymap : int StringMap.t = <abstr>

# StringMap.find "Adams" mymap;;
- : int = 17
# StringMap.find "Douglas" mymap;;
- : int = 42
# StringMap.find "Slarti" mymap;;
Exception: Not_found.
```

Maps

- ▶ Fully functional: *Map.add* takes a key, a value, and a map and returns a new map that also includes the given key/value pair.
- ▶ Needs a totally ordered key type. *Pervasives.compare* usually does the job (returns -1 , 0 , or 1), but you may also supply your own.
- ▶ Uses balanced trees, so searching and insertion is $O(\log n)$.

Depth-First Search Revisited

Previous version

```
let rec dfs = function
  ([] , _ , visited) -> List.rev visited
| (n :: nodes , edges , visited) ->
  if List.mem n visited then
    dfs(nodes , edges , visited)
  else
    dfs(successors(n , edges) @ nodes , edges , n :: visited);;
```

was not very efficient, but good enough for small graphs.

Would like faster *visited* test and *successors* query.

Depth-First Search Revisited

Second version:

- ▶ use a Map to hold a list of successors for each node
- ▶ use a Set (valueless Map) to remember of visited nodes

```
(* Map with strings a keys *)
module StringMap = Map.Make(struct
  type t = string
  let compare x y = Pervasives.compare x y
end)

(* Set of strings *)
module StringSet = Set.Make(struct
  type t = string
  let compare x y = Pervasives.compare x y
end)
```

Depth-First Search Revisited

```
let top_sort_map edges =
  (* Create an empty successor list for each node *)
  let succs = List.fold_left
    (fun map (s,d) ->
      StringMap.add d [] (StringMap.add s [] map)
    ) StringMap.empty edges
  in
  (* Build the successor list for each source node *)
  let succs = List.fold_left
    (fun succs (s, d) ->
      let ss = StringMap.find s succs
      in StringMap.add s (d::ss) succs
    ) StringMap.empty edges
  in
  (* Visit recursively, storing each node after visiting successors *)
  let rec visit (order, visited) n =
    if StringSet.mem n visited then
      (order, visited)
    else
      let (order, visited) = List.fold_left
        visit (order, StringSet.add n visited)
        (StringMap.find n succs)
      in (n::order, visited)
  in
  (* Visit the source of each edge *)
  fst (List.fold_left visit ([] , StringSet.empty) (List.map fst edges))
```

Imperative Features

```
# 0 ; 42;;          (* ";" means sequencing *)
Warning S: this expression should have type unit.
- : int = 42

# ignore 0 ; 42;;      (* ignore is a function: 'a -> unit *)
- : int = 42
# () ; 42;;          (* () is the literal for the unit type *)
- : int = 42

# print_endline "Hello World!";;    (* Print; result is unit *)
Hello World!
- : unit = ()
# print_string "Hello " ; print_endline "World!";;
Hello World!
- : unit = ()

# print_int 42 ; print_newline ();;
42
- : unit = ()
# print_endline ("Hello " ^ string_of_int 42 ^ " world!");;
Hello 42 world!
- : unit = ()
```

Arrays

```
# let a = [| 42; 17; 19 |];;                      (* Array literal *)
val a : int array = [|42; 17; 19|]
# let aa = Array.make 5 0;;                         (* Fill a new array *)
val aa : int array = [|0; 0; 0; 0; 0|]

# a.(0);;                                         (* Random access *)
- : int = 42
# a.(2);;
- : int = 19
# a.(3);;
Exception: Invalid_argument "index out of bounds".

# a.(2) <- 20;;                                  (* Arrays are mutable! *)
- : unit = ()
# a;;
- : int array = [|42; 17; 20|]

# let l = [24; 32; 17];;
val l : int list = [24; 32; 17]
# let b = Array.of_list l;;                        (* Array from a list *)
val b : int array = [|24; 32; 17|]

# let c = Array.append a b;;                      (* Concatenation *)
val c : int array = [|42; 17; 20; 24; 32; 17|]
```

Arrays vs. Lists

	Arrays	Lists
Random access	$O(1)$	$O(n)$
Appending	$O(n)$	$O(1)$
Mutable	Yes	No

Useful pattern: first collect data of unknown length in a list then convert it to an array with *Array.of_list* for random queries.

Again With The Depth First Search

Second version used a lot of *mem*, *find*, and *add* calls on the string map, each $O(\log n)$. Can we do better?

Solution: use arrays to hold adjacency lists and track visiting information.

Basic idea: number the nodes, build adjacency lists with numbers, use an array for tracking visits, then transform back to list of node names.

DFS with Arrays (part I)

```
let top_sort_array edges =
(* Assign a number to each node *)
let map, nodecount =
List.fold_left
  (fun nodemap (s, d) ->
    let addnode node (map, n) =
      if StringMap.mem node map then (map, n)
      else (StringMap.add node n map, n+1)
    in
    addnode d (addnode s nodemap)
  ) (StringMap.empty, 0) edges
in

let successors = Array.make nodecount [] in
let name = Array.make nodecount "" in

(* Build adjacency lists and remember the name of each node *)
List.iter
  (fun (s, d) ->
    let ss = StringMap.find s map in
    let dd = StringMap.find d map in
    successors.(ss) <- dd :: successors.(ss);
    name.(ss) <- s;
    name.(dd) <- d;
  ) edges;
```

DFS with Arrays (concluded)

```
(* Visited flags for each node *)
let visited = Array.make nodecount false in

(* Visit each of our successors if we haven't done so yet *)
(* then record the node *)
let rec visit order n =
  if visited.(n) then order
  else (
    visited.(n) <- true;
    n :: (List.fold_left visit order successors.(n))
  )
in

(* Compute the topological order *)
let order = visit [] 0 in

(* Map node numbers back to node names *)
List.map (fun n -> name.(n)) order
```

Hash Tables

```
# module StringHash = Hashtbl.Make(struct
    type t = string                                (* type of keys *)
    let equal x y = x = y                          (* use structural comparison *)
    let hash = Hashtbl.hash                         (* generic hash function *)
  end);;
module StringHash :
sig
  type key = string
  type 'a t
  val create : int -> 'a t
  val clear : 'a t -> unit
  val copy : 'a t -> 'a t
  val add : 'a t -> key -> 'a -> unit
  val remove : 'a t -> key -> unit
  val find : 'a t -> key -> 'a
  val find_all : 'a t -> key -> 'a list
  val replace : 'a t -> key -> 'a -> unit
  val mem : 'a t -> key -> bool
  val iter : (key -> 'a -> unit) -> 'a t -> unit
  val fold : (key -> 'a -> 'b -> 'b) -> 'a t -> 'b -> 'b
  val length : 'a t -> int
end
```

Hash Tables

```
# let hash = StringHash.create 17;; (* initial size estimate *)
val hash : '_a StringHash.t = <abstr>

# StringHash.add hash "Douglas" 42;; (* modify the hash table *)
- : unit = ()

# StringHash.mem hash "foo";;                      (* is "foo" there? *)
- : bool = false
# StringHash.mem hash "Douglas";;                  (* is "Douglas" there? *)
- : bool = true

# StringHash.find hash "Douglas";;                (* Get value *)
- : int = 42

# StringHash.add hash "Adams" 17;;    (* Add another key/value *)
- : unit = ()

# StringHash.find hash "Adams";;
- : int = 17
# StringHash.find hash "Douglas";;
- : int = 42
# StringHash.find hash "Slarti";;
Exception: Not_found.
```

Modules

Each source file is a module and everything is public.

foo.ml

```
(* Module Foo *)  
  
type t = { x : int ; y : int };;  
let sum c = c.x + c.y;;
```

bar.ml

```
(* The dot notation *)  
  
let v = { Foo.x = 1 ;  
          Foo.y = 2 };;  
print_int (Foo.sum v);;
```

To compile and run these,

```
$ ocamlc -c foo.ml  
      (creates foo.cmi foo.cmo)  
$ ocamlc -c bar.ml  
      (creates bar.cmi bar.cmo)  
$ ocamlc -o ex foo.cmo bar.cmo  
$ ./ex  
333
```

```
(* Create a short name *)  
  
module F = Foo;;  
print_int (F.sum v);;  
  
(* Import every name from  
   a module with "open" *)  
  
open Foo;;  
print_int (sum v);;
```

Separating Interface and Implementation

stack.mli

```
type 'a t

exception Empty

val create : unit -> 'a t
val push : 'a -> 'a t -> unit
val pop : 'a t -> 'a
val top : 'a t -> 'a
val clear : 'a t -> unit
val copy : 'a t -> 'a t
val is_empty : 'a t -> bool
val length : 'a t -> int
val iter : ('a -> unit) ->
           'a t -> unit
```

stack.ml

```
type 'a t =
  { mutable c : 'a list }

exception Empty

let create () = { c = [] }
let clear s = s.c <- []
let copy s = { c = s.c }
let push x s = s.c <- x :: s.c

let pop s =
  match s.c with
    hd::tl -> s.c <- tl; hd
  | []       -> raise Empty

let top s =
  match s.c with
    hd::_ -> hd
  | []       -> raise Empty

let is_empty s = (s.c = [])
let length s = List.length s.c
let iter f s = List.iter f s.c
```

Part IV

A Complete Interpreter in Three Slides

The Scanner and AST

scanner.mll

```
{ open Parser }

rule token =
  parse [ ' ' '\t' '\r' '\n'] { token lexbuf }
    | '+' { PLUS }
    | '-' { MINUS }
    | '*' { TIMES }
    | '/' { DIVIDE }
    | ['0'-'9']+ as lit { LITERAL(int_of_string lit) }
    | eof { EOF }
```

ast.mli

```
type operator = Add | Sub | Mul | Div

type expr =
  Binop of expr * operator * expr
  | Lit of int
```

The Parser

parser.mly

```
%{ open Ast %}

%token PLUS MINUS TIMES DIVIDE EOF
%token <int> LITERAL

%left PLUS MINUS
%left TIMES DIVIDE

%start expr
%type <Ast.expr> expr

%%

expr:
    expr PLUS    expr { Binop($1, Add, $3) }
  | expr MINUS   expr { Binop($1, Sub, $3) }
  | expr TIMES   expr { Binop($1, Mul, $3) }
  | expr DIVIDE  expr { Binop($1, Div, $3) }
  | LITERAL          { Lit($1) }
```

The Interpreter

calc.ml

```
open Ast

let rec eval = function
  | Lit(x) -> x
  | Binop(e1, op, e2) ->
    let v1 = eval e1 and v2 = eval e2 in
    match op with
      | Add -> v1 + v2
      | Sub -> v1 - v2
      | Mul -> v1 * v2
      | Div -> v1 / v2

let _ =
  let lexbuf = Lexing.from_channel stdin in
  let expr = Parser.expr Scanner.token lexbuf in
  let result = eval expr in
  print_endline (string_of_int result)
```

Compiling the Interpreter

```
$ ocamllex scanner.mll # create scanner.ml
8 states, 267 transitions, table size 1116 bytes
$ ocamlyacc parser.mly # create parser.ml and parser.mli
$ ocamlc -c ast.mli      # compile AST types
$ ocamlc -c parser.mli # compile parser types
$ ocamlc -c scanner.ml # compile the scanner
$ ocamlc -c parser.ml  # compile the parser
$ ocamlc -c calc.ml     # compile the interpreter
$ ocamlc -o calc parser.cmo scanner.cmo calc.cmo
$ ./calc
2 * 3 + 4 * 5
26
$
```
