1 Introduction

2 Lexical conventions

There are five kinds of tokens in the language, namely (1) identifiers, (2) keywords, (3) constants, (4) expression operators, and (5) other separators. At a given point in the parsing, the next token is chosen as to include the longest possible string of characters forming a token.

2.1 Character set

QLang supports a subset of ASCII; that is, allowed characters are as well as tabulations \t, spaces, and line returns \n and \r.

2.2 Comments

Comments start with a # sign, which then extends until the next carriage return. Multiline comments are not supported.

2.3 Identifier (names)

An identifier is an arbitrarily long sequence of alphabetic and numeric characters, where _ is included as “alphabetic”. It must start with a lowercase or uppercase letter, i.e. one of a-zA-Z.

The language is case-sensitive: hullabaloo and hullABaLoo are considered as different.

2.4 Keywords

The following identifiers as reserved for keywords: using them as function of variable name will result in an error at compilation time.

pi e
int float comp rvect cvect mat
true false
if elif else
def for from to by while break
or and xor
not re im norm isunit trans det adj conj sin cos tan exp

2.5 Constants

There are four sorts of constants in the language, namely integer, float, complex and identifier constants. The first are comprised of any sequence of integers of the form 0|([1-9][0-9]*) (recall that integers are non-negative), and have type int. The second are of type float and have the form R, while the third are of type com and have the form R|R+Ri|Ri where R consists of a (i) sign, (ii) an integer part followed by (iii) a point, (iv) a decimal part, then (v) either a e or a E followed by an exponent part, possibly signed. (i) and (v) are optional, and either (ii) or (iv) can be missing as well. In more detail, R is defined as [+-]{0,1}(()(A.B*1.B+)([eE][+-]?B*)?)|A[eE][+-]?B+ and A =0|([1-9]B*), B =0|[1-9] (that is, R matches a real number such as 2.78e5, 1.5E-1 or 10.25).check this paragraph.
Finally, the identifier constants are a subset of the reserved keywords, and include:

- **e** the base of natural logarithm \( e = \sum_{k=0}^{\infty} \frac{1}{k!} \). Equivalent to \( \exp(1) \); has type **com**.
- **pi** the constant \( \pi \). Has type **com**.
- **true** represents the Boolean value **true**. Stored internally as **int** 1.
- **false** represents the Boolean value **false**. Stored internally as **int** 0.

### 2.6 Elementary operations and spacing

An operation, or language elementary unit, starts from the end of the previous one, and ends whenever a semicolon is encountered. Whitespace does not play any role, except as separators between tokens; in particular, indentation is arbitrary.

### 3 Objects and types

#### 3.1 Objects and lvalues

As in C, “an object is a manipulatable region of storage; an lvalue is an expression referring to an object.”

#### 3.2 Valid types

The language features 5 elementary types, namely **int**, **float**, **com**, **qub**, **mat**. (In particular, column and row vectors are represented respectively as \( n \times 1 \) or \( 1 \times n \) matrices.) Is also valid any type that inductively can be built from an a valid type as follows:

- **elementary types** are valid;
- an **array** of a valid type is valid. Arrays have fixed size (that must be declared at compilation time), and are comprised of elements of a single, fixed valid type;
- a **function** taking as input a fixed number of elements from (non-necessarily identical) valid types, and returning a valid type.

### 4 Conversions

Applying unary or binary operators to some values may cause an implicit conversion of their operands. In this section, we list the possible conversions, and their expected result – any conversion not listed here is impossible, and attempting to force it would generate a compilation error.

- **int \to float**, **float \to com**, **int \to com**.
- **com \to float**: the imaginary part of the complex number is dropped (will generate a warning).
- **float \to int**: the floating number is rounded towards zero.
- **com \to int**: equivalent to **com \to float \to int**.
- **com \to mat**: the floating number \( z \) becomes the \( 1 \times 1 \) matrix \([z]\) (will generate a warning).
- **float \to mat**: the floating number \( x \) becomes the \( 1 \times 1 \) matrix \([x]\) (will generate a warning).
- **int \to mat**: the integer \( a \) becomes the \( 1 \times 1 \) matrix \([a]\) (will generate a warning).
5  Expressions

5.1  Operator Precedence

<table>

</tr>
</tbody>
</table>

5.2  Literals

Literals are integers, floats, complex numbers, qubits, and matrices, as well as the built-in constants of the language (e.g. pi). Integers are of type int, floats are of type float, complex numbers are of type com, qubits are of type qub, and matrices are of type mat. The built-in constants have pre-determined types described above (e.g. pi is of type float).

The remaining major subsections of this section describe the groups of expression operators, while the minor subsections describe the individual operators within a group.

5.3  Primary Expressions

5.3.1  identifier

Identifiers are primary expression. All identifiers have an associated type that is given to them upon declaration (e.g. float ident declares an identifier named ident that is of type float).

5.3.2  literals

Literals are primary expression. They are described above.

5.3.3  (expression)

Parenthesized expressions are primary expressions. The type and value of a parenthesized expression is the same as the type and value of the expression without parenthesis. Parentheses allow expressions to be evaluated in a desired precedence. Parenthesized expressions are evaluated relative to each other starting with the expression that is nested the most deeply and ending with the expression that is nested the least deeply (i.e. the shallowest).

5.3.4  primary-expression(expression-list)

Primary expressions followed by a parenthesized expression list are primary expressions. Such primary expressions can be used in the declaration of functions or function calls. The expression list must consist of one or more expressions separated by commas. If being used in function declarations, they must be preceded by the correct function declaration syntax and each expression in the expression list must evaluate to a type followed by an identifier. If being used in function calls each expression in the expression list must evaluate to an identifier.
5.3.5  **primary-expression[expression-list]**

Primary expressions followed by a bracketed expression list are primary expressions. Such primary expressions can be used in the declaration of matrices and arrays or to access an element of a matrix or array. The expression list must consist of one (for matrices and arrays) or two (for matrices) expressions separated by commas, and must evaluate to **int**.

5.3.6  **[expression-elementlist]**

Expression element lists in brackets are primary expressions. Such primary expressions are used to define matrices and therefore are of type **mat**. The expression element list must consist of one or more expressions separated by commas or semi-colons. Commas separate expressions into matrix columns and colons separate expressions into matrix rows. The expressions must evaluate to the same type and can be of type **int, float, com, or mat**. Additionally, the number of expressions in each row of the matrix must be the same. An example matrix is shown below.

```cpp
int a = 3;
int b = 12;
mat my_matrix = [ 0+1, 2, a: 5−1, 2*3−1, 12/2];
```

5.3.7  **<expression>**

Expressions with a less than sign on the left and a bar on the right are primary expression. Such expressions are used to define qubits and therefore are of type **qub**. The notation is meant to mimic the 'bra-' of 'bra-ket' notation and can therefore be thought of as a row vector representation of the given qubit. Following 'bra-ket' notation, the expression must evaluate to an integer literal of only 0's and 1's, which represents the state of the qubit. An example 'bra-' qubit is shown below.

```cpp
qub b_qubit = <0100>;
```

5.3.8  **|expression>**

Expressions with a bar on the left and a greater than sign on the right are primary expression. All of the considerations are the same as for **<expression>**, except that this notation mimics the 'ket' of 'bra-ket' notation and can therefore be thought of as a column vector representation of the given qubit. An example 'ket-' qubit is shown below.

```cpp
int a = 001;
qub k_qubit = |a>;
```

5.4  **Unary Operators**

5.4.1  **not expression**

The result is a Boolean indicating the logical **not** of the **expression**. The type of the expression must be **int** or **float**. In the **expressions**, 0 is considered false and all other values are considered true.
5.4.2 re expression
The result is the real component of the expression. The type of the expression must be com. The result has the same type as the expression (it is a complex number with 0 imaginary component).

5.4.3 im expression
The result is the imaginary component of the expression. The type of the expression must be com. The result has the same type as the expression (it is a complex number with 0 real component).

5.4.4 norm expression
The result is the norm of the expression. The type of the expression must be mat, com, qub or float. The result has type float, and corresponds to the 2-norm; in the case of com or float, this coincides with respectively the module and absolute value.

5.4.5 isunit expression
The result is a Boolean indicating if it is true or false that the expression is a unit matrix. The type of the expression must be mat.

5.4.6 trans expression
The result is the transpose of the expression. The type of the expression must be mat. The result has the same type as the expression.

5.4.7 det expression
The result is the determinant of the expression. The type of the expression must be mat. The result has type float if the expression is an integer matrix or float matrix and type com if the expression is a complex number matrix.

5.4.8 adj expression
The result is the adjoint of the expression. The type of the expression must be mat. The result has the same type as the expression.

5.4.9 conj expression
The result is the complex conjugate of the expression. The type of the expression must be com or mat. The result has the same type as the expression.

5.4.10 sin expression
The result is the evaluation of the trigonometric function sine on the expression. The type of the expression must be int, float, or com. The result has type float if the expression is of type int or float and type com if the expression is of type com.
5.4.11 cos expression

The result is the evaluation of the trigonometric function cosine on the expression. The type of the expression must be int, float, or com. The result has type float if the expression is of type int or float and type com if the expression is of type com.

5.4.12 tan expression

The result is the evaluation of the trigonometric function tangent on the expression. The type of the expression must be int, float, or com. The result has type float if the expression is of type int or float and type com if the expression is of type com. (If an error occurred because of a division by zero, a runtime exception is raised.)

5.5 Binary Operators

5.5.1 expression ^ expression

The result is the exponentiation of the first expression by the second expression. The types of the expression must be of type int, float, or com. If the expressions are of the same type, the result has the same type as the expressions. Otherwise, if at least one expression is a com, the result is of type com; if neither expressions are comp, but at least one is float, the result is of type float.

5.5.2 expression * expression

The result is the product of the expressions. The type considerations are the same as they are for expression ^ expression.

5.5.3 expression / expression

The result is the quotient of the expressions, where the first expression is the dividend and the second is the divisor. The type considerations are the same as they are for expression ^ expression. Integer division is rounded towards 0 and truncated. (If an error occurred because of a division by zero, a runtime exception is raised.)

5.5.4 expression % expression

The result is the remainder of the division of the expressions, where the first expression is the dividend and the second is the divisor. The sign of the dividend and the divisor are ignored, so the result returned is always the remainder of the absolute value (or module) of the dividend divided by the absolute value of the divisor. The type considerations are the same as they are for expression ^ expression.

5.5.5 expression + expression

The result is the sum of the expressions. The types of the expressions must be of type int, float, com, mat or qub. If at least one expression is a com, the result is of type com; if neither expressions are comp, but at least one is float, the result is of type float. Qubits and matrices are special and can only be summed with within operands of the same type (and, in the case of matrices, dimensions).
5.5.6  *expression - expression*

The result is the difference of the first and second *expression*. The type considerations are the same as they are for *expression + expression*.

5.5.7  *expression @ expression*

The result is the tensor product of the first and second *expressions*. The expressions must be of type of *mat*. The result has the same type as the *expression*.

5.5.8  *expression eq expression*

The result is a Boolean indicating if it is true or false that the two *expression* are structurally equivalent. The type of the expressions must be the same.

5.5.9  *expression lt expression*

The result is a Boolean indicating if it is true or false that the first *expression* is less than the second. The type of the expressions must be *int* or *float* and must be the same.

5.5.10  *expression gt expression*

The result is a Boolean indicating if it is true or false that the first *expression* is greater than the second. The type of the expressions must be *int* or *float* and must be the same.

5.5.11  *expression leq expression*

The result is a Boolean indicating if it is true or false that the first *expression* is less than or equal to the second. The type of the expressions must be *int* or *float* and must be the same.

5.5.12  *expression geq expression*

The result is a Boolean indicating if it is true or false that the first *expression* is greater than or equal to the second. The type of the expressions must be *int* or *float* and must be the same.

5.5.13  *expression or expression*

The result is a Boolean indicating the logical *or* of the *expressions*. The type of the expressions must be *int* or *float* and must be the same. In the *expressions*, 0 is considered *false* and all other values are considered *true*.

5.5.14  *expression and expression*

The result is a Boolean indicating the logical *and* of the *expressions*. The type considerations are the same as they are for *expression or expression*.

5.5.15  *expression xor expression*

The result is a Boolean indicating the logical *xor* of the *expressions*. The type considerations are the same as they are for *expression or expression*. 
5.6 Assignment Operators
Assignment operators have left associativity

5.6.1 lvalue = expression
The result is the assignment of the expression to the lvalue. The lvalue must have been previously declared. The type of the expression must be of the same that the lvalue was declared as. Recall, lvalues can be declared as int, float, comp, mat, and qubit.

6 Declarations
Declarations are used within functions to specify how to interpret each identifier. Declarations have the form

\[
declaration:
\text{type-specifier} \ \text{declarator-list}
\]

6.1 Type Specifiers
There are five main type specifiers:
\text{type-specifier:}
\begin{itemize}
  \item int
  \item float
  \item com
  \item mat
  \item qub
\end{itemize}

6.2 Declarator List
The declarator-list consist of either a single declarator, or a series of declarators separated by commas.

\[
declarator-list:
\text{declarator}
\text{declarator}, \text{declarator-list}
\]

A declarator refers to an object with a type determined by the type-specifier in the overall declaration. Declarators can have the following form

\[
declarator:
\text{identifier}
\text{declarator} \ ( )
\text{declarator} \ [ \text{constant-expression} ]
( \text{declarator} )
\]
6.3 Meaning of Declarators

Each declarator that appears in an expression is a call to create an object of the specified type. Each declarator has one identifier, and it is this identifier that is now associated with the created object.

If declarator D has the form

\[ D(\ ) \]

then the contained identifier has the type "function" that is returning an object. This object has the type which the identifier would have had if the declarator had just been D.

If a declarator has the form

\[ D[\text{constant-expression}] \]

or

\[ D[\ ] \]

then it is a declarator whose identifier is of type "array". In the first case, the constant-expression is an expression whose value can be defined at compile time. The type of that constant-expression is int. In the second case, the constant expression 1 is used.

An array may be constructed from one of the basic types, or from another array.

Parentheses in declarators do not change the the type of contained identifier, but can affect the relations between the individual components of the declarator.

Not all possible combinations of the above syntax are permitted. There are certain restrictions such as how array of functions cannot be declared.

7 Statements

7.1 Expression statements

Expression statements are the building blocks of an executable program. As the name suggests, expression statements are nothing but expressions, delimited by semicolons. Expressions can actually be declarations, assignments, operations or even function calls. For example,

\[ x = a + 3; \]

is a valid expression statement, and so is

\[ \text{print}(a); \]
7.2 The if-elif-else statement

The *if-elif-else* statement is used for selectively executing statements based on some condition. Essentially, if the condition following the *if* keyword is satisfied, the specified statements get executed. To specify what happens if the condition does not evaluate to true, we have the *else* keyword. In case we want to evaluate more than one condition at a time, we also have the *elif* keyword. So an *if* can be followed by any number of *elifs*, and at most one else block which is the end of the construct. The statements following the *else* are executed only if neither of the conditions specified before that evaluate to true.

```plaintext
if ( condition ) {
} elif ( condition ) {
} else {
}
```

Example:
```plaintext
if ( x==5) {
   print("x is 5");
} elif (x==3) {
   print("x is 3");
} else {
   print("x is neither 5 nor 3")
}
```

7.3 The for loop

The for statement is used for executing a set of statements a specified number of times. The statements within the for loop are executed as long as the value of the variable is within the specified range. As soon as the value goes out of range, control comes out of the for loop. To ensure termination, each iteration of the for loop increments/decrements the value of the variable, bringing it one step closer to the final value that is to be achieved.

By default, increment or decrement is by 1. However, if the desired increment is something other than one, the *by* keyword lets you specify that explicitly.

An example of for loop, increment by 2 is as follows:

```plaintext
for k from 1 to 10 by 2 {
}
```

8 Scope rules

Name bindings have a block scope. That is to say, the scope of a name binding is limited to a section of code that is grouped together. That name can only be used to refer to associated entity
in that block of code. Blocks of code in QLang are delimited by the opening curly brace ('{') at
the start of the block, and the closing curly brace ('}') at the end of the block.

Within a program, variables may be declared and/or defined in various places. The scope of
each variable is different, depending on where it is declared. There are three primary scope rules.

If a variable is defined at the outset/outer block of a program, it is visible everywhere in the
program.

If a variable is defined as a parameter to a function, or inside a function/block of code, it is
visible only within that function.

Declarations made after a specific declaration are not visible to it, or to any declarations before
it.

For instance, consider the following snippet.

```qlang
int x = 5;
int y = x + 10;  # this works
int z = a + 100;  # this does not
int a = 200;
```

9 Constant expressions

In order to facilitate efficiency in writing expression, the language introduces various mathematical
constants such as $\pi$, $e$ and matrices such Pauli matrices and Hadamard matrices which are frequently
used in quantum computation. The keywords $I$, $X$, $Y$, $Z$, and $H$ are reserved for this expressions.

$$
I = \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix} \quad X = \begin{bmatrix} 0 & 1 \\ 1 & 0 \end{bmatrix} \quad Z = \begin{bmatrix} 1 & 0 \\ 0 & -1 \end{bmatrix} \quad Y = \begin{bmatrix} 0 & -i \\ i & 0 \end{bmatrix}.
$$

The Hadamard gate is defined by the matrix:

$$
H = \frac{1}{\sqrt{2}} \begin{bmatrix} 1 & 1 \\ 1 & -1 \end{bmatrix}.
$$

10 Examples

We present some examples that illustrates the use of QLang in solving quantum computing problems.

10.1 Solving Quantum Computation Problem

10.1.1 Problem1

Evaluate the following expressions: a. $(H \otimes X)|00\rangle$ b. $\langle 101|000\rangle$ c. $\langle 01|H \otimes H|01\rangle$
2 \textbf{def} pseudo = evaluate (){

4 \quad \# \text{ a quit type declaration follows dirac notation}
5 \quad \textbf{qub} mat0 = |00>;

6 \quad \# \text{ Both X and H are constant with type mat and}
8 \quad \# \text{@ corresponds to tensor product.}
9 \quad \textbf{mat} HX = H @ X;
10 \quad \text{pseudo} = HX * \text{mat0};
12 \}

10.1.2 Problem 2

Find the matrix corresponding to the quantum circuit:

![Quantum Circuit](image)

Figure 1: Quantum Circuit implementing series of control gates

1 \textbf{def} circuitMat = findMatrix (){

3 \quad \# \text{ all basis qubit in 2 dimension}
4 \quad \textbf{qub} mat0=|00>;
5 \quad \textbf{qub} mat1=|01>;
6 \quad \textbf{qub} mat2=|10>;
7 \quad \textbf{qub} mat3=|11>;

9 \quad \# \text{controlled not matrix}
10 \quad \textbf{mat} CNOT = [1,0,0,0,0,0,0,0,0,0,0,0,0,1,0,1,0,1,0]
11 \quad \# \text{controlled hadmard matrix}
13 \quad \textbf{mat} HNOT = [1/sqrt(2),0,1/sqrt(2),0,1,0,0,0,1,0,0,1,0,0,0,0,0,0,0]
15 \quad \# \text{composition of control gates}
16 \quad \textbf{mat} allGates = CNOT * HNOT * CNOT
17 \quad \# \text{Matrix corresponding to the circuit}
18 \quad \textbf{circuitMat} = [allGates*mat0:allGates*mat1:allGates*mat2:allGates*mat3]
19
10.1.3 Problem 3

Consider the circuit and show the probabilities of outcome 0 where $|\Psi_{in}\rangle = |1\rangle$

```
def probability = outcomeZero()

    # top and bottom qubits
    qub top = |0>;
    qub bottom = |1>;

    # Applying H on top qubit
    mat output = (H @ I) * (top @ bottom);

    # Controlled Not operator
    mat CNOT = [I, [0,0,0,0]: [0,0,0,0], X];

    # Controlled Y operator
    mat CY = [Y,[0,0,0,0]:[0,0,0,0], I];

    # Applying Control Operators
    output = (CY)*(CNOT)*output

    # Applying measurement operator on top qubit |0> <0|
    mat M = ([0>*<0] @ I)

    # state after applying measurement operator on top qubit
    outcome = M * output;

    # probability of outcome
    probability = norm(outcome);
```

Figure 2: Quantum Circuit
10.2 Simulation of Quantum Algorithm

10.2.1 Deutsch Jozsa Algorithm

```python
def outcome = deutschJozsa(qub top , mat U){
    # in corresponds to the qubit in top register
    # input is the tensor product of top register and bottom register
    mat input= top @ |1>;

    # application of Hadamard gate on both top and bottom inputs
    input = (H @ H)*input;

    # application of U gate on the above result
    input = U * input;

    # application of Hadamard gate on the top register
    input = (H @ I)*input;

    # application of measurement operator on the top register
    # top * Adj (top) corresponds to the Measurement operator
    input=(top*Adj(top)@ I)*input;

    #after the measurement is applied, check if the input is 0 or not
    if (input == 0){
        #probability of outcome 0 is 0
        outcome = 0;
    } else{
        # probability of outcome 0 is 1
        outcome = 1;
    }
}
```

10.2.2 Grover’s Search Algorithm

```python
def result = grover (quit top , int x0){
    # returns the probability to find x0 for a function f such that f(x0)=1
    # x0 can be x0=0,1,?,2^n−1
    # this is a special case where n=1

    # qubit in the bottom register
    qub bottom = |1>;

    # tensor product of top and bottom qubit
    mat input = top @ bottom;

    #application of Hadamard
```
Figure 3: Grover Algorithm Circuit

\begin{verbatim}
input = (H @ H) * input;

#define S
mat S = [1, 0:0 -1]

# k : number of time grover operator is applied
# for n > 1 k=ceil((pi*2^(n/2))/4);
int k = 1;

#define O operator such that O|x>|q>=|x>|q mod f(x)> or O|x>=(-1)f(x)|x>
# for n > 1 O = I(2^(n1+1));
mat O = I;
O(x0+1, x0+1) = -1;

# Grover iteration matrix
mat GO = (G*O)^k;

# After application of Grover iteration matrix
mat output = GO * input;
result = (H @ H) * output;
\end{verbatim}
