#### **Dot Product**

```
#include <stdio.h>
int main()
{
 double a[256], b[256], sum;
  int i, n = 256;
  for (i = 0; i < n; i++) {
    a[i] = i * 0.5;
    b[i] = i * 2.0;
  }
  sum = 0.0;
  for (i = 0 ; i < n ; i++ )
    sum += a[i] * b[i];
  printf("sum = \%f n", sum);
 return 0;
}
```

#### **Dot Product**

```
#include <omp.h>
#include <stdio.h>
int main()
  double a[256], b[256], sum;
  int i, n = 256;
  for (i = 0; i < n; i++) {
    a[i] = i * 0.5;
    b[i] = i * 2.0;
  }
  sum = 0.0:
# pragma omp parallel for reduction(+:sum)
  for (i = 0; i < n; i++)
    sum += a[i] * b[i];
  printf("sum = \%f n", sum);
  return 0;
}
```

#### **OpenMP version**

gcc -fopenmp -o dot dot.c OpenMP pragma tells the compiler to

- Execute the loop's iterations in parallel (multiple threads)
- Sum each thread's results

# Part II

# Java's Support for Concurrency

## **Thread Basics**

How to create a thread:

```
class MyThread extends Thread {
  public void run() { // A thread's "main" method
    /* thread body */
  }
}
MyThread mt = new MyThread; /* Create thread */
mt.start(); /* Start thread at run() */
// Returns immediately}
```

Threads are multiple contexts/program counters running within the same memory space

All objects shared among threads by default

Any thread can access any object/method: no notion of ownership

# implements Runnable vs. extends Thread

An alternative:

```
class MyRunnable implements Runnable {
   public void run() {
      /* thread body */
   }
}
Thread t = new Thread(new MyRunnable());
t.start(); /* Starts thread at run() */
// Returns immediately}
```

Advantage: class implementing Runnable can be derived from some other class (i.e., not just from Thread).

Disadvantage: "this" is not a Thread so, e.g., sleep() must be called with Thread.currentThread().sleep().

・ロト・一部・・ヨト・ヨト ヨー うらつ

# The Sleep Method

```
class Sleeper extends Thread {
 public void run() {
    for (;;) {
      try {
        sleep(1000); // Pause for at least a second
      } catch (InterruptedException e) {
        return; // caused by thread.interrupt()
      }
      System.out.println("tick");
   }
 }
3
```

▲□▶▲□▶▲□▶▲□▶ □ のQの

Does this print "tick" once a second?

#### A Clock?

```
class PrintingClock implements Runnable {
 public void run() {
    for (;;) {
      java.util.Date now = new java.util.Date();
      System.out.println(now.toString());
      try {
        Thread.currentThread().sleep(1000);
      } catch (InterruptedException e) {}
   }
 }
}
public class Clock {
 public static void main(String args[]) {
    Thread t = new Thread(new PrintingClock());
    t.start();
 }
```

# Motivation for Synchronization

Something you might want to implement:

```
class ScoreKeeper {
  int _score = 0;
  void score(int v) {
    int tmp = _score;
    tmp += v;
    _score = tmp;
  }
}
```

What could the final score be if two threads simultaneously call score(1) and score(2)?

double d;

Thread 1Thread 2i = 10;i = 20;d = 10.0;d = 20.0;

### Per-Object Locks

Each Java object has a lock that may be owned by at least one thread

# A thread waits if it attempts to obtain an already-obtained lock

The lock is a counter: one thread may lock an object more than once

▲□▶▲□▶▲□▶▲□▶ □ のQの

# The Synchronized Statement

A synchronized statement waits for an obtains an object's lock before running its body

・ロト・一部・・ヨト・ヨト ヨー うらつ

```
Counter mycount = new Counter;
synchronized(mycount) {
  mycount.count();
}
```

Releases the lock when the body terminates.

Choice of object to lock is by convention.

### Synchronized Methods

```
class AtomicCounter {
   private int _count;
   public synchronized void count() {
     _count++;
   }
}
```

synchronized attribute equivalent to enclosing body with synchronized (this) statement.

Most common way to achieve object-level atomic operations.

Implementation guarantees at most one thread can run a synchronized method on a particular object at once

#### Deadlock

3

▲□▶▲□▶▲□▶▲□▶ □ のQの

Rule: always acquire locks in the same order.

# Synchronization

Say you want a thread to wait for a condition before proceeding.

An infinite loop may deadlock the system (e.g., if it's using cooperative multitasking).

while (!condition) {}

Calling yield avoids deadlock, but is inefficient:

while (!condition) yield();

シック・ 川 ・ ・ 川 ・ ・ 一 ・ シック

Java's Solution: wait() and notify()

wait() like yield(), but requires other thread to reawaken it

while (!condition) wait();

Thread that changes the condition calls notify() to resume the thread.

Programmer responsible for ensuring each wait() has a matching notify().

I often have books delivered to the CS department office. This operation consists of the following steps:

- 1. Place the order
- 2. Retrieve the book from the CS department office

・ロト ・ 同 ト ・ ヨ ト ・ ヨ ・ うへつ

3. Place book on bookshelf

Obviously, there's a delay between steps 1 and 2.

## The Implementation in the CS Office

This "order, retrive, file" thread is running in me, and it needs to wait for the book to arrive.

I could check the department office every minute, hour, day, etc. to see if the book has come in, but this would be waste of time (but possibly good exercise).

Better approach would be to have the "receiving" process alert me when the book actually arrives.

### A Flawed Implementation

What happens if the book is delivered before the main thread starts waiting?

Answer: the "notify" instruction does not wake up any threads. Later, the main thread starts to wait and will never be awakened.

As if Alice came to my office to tell me when I was not there.

#### Harder Problem

Sometimes I have a number of books on order, but Alice only tells me a book has arrived. How do I handle waiting for a number of books?

Last solution assumed a single source of notify(); not true in general.

Two rules:

1. Use notifyAll() when more than one thread may be waiting

・ロト ・ 同 ト ・ ヨ ト ・ ヨ ・ うへつ

2. Wait in a while if you could be notified early, e.g.,

while (!condition)
 wait();

### The multi-book problem

```
class Mailbox {
    int book;
    Mailbox() { book = -1; }
    void receive_book(int b) { book = b; }
    int which_book() { return book; }
}
```

This is not thread-safe: we'll need to synchronize all access to it.

▲□▶▲□▶▲□▶▲□▶ □ のQの

#### The multi-book problem

The Delivery class also tells the mailbox which book it got.

▲□▶▲□▶▲□▶▲□▶ □ のQの

```
class Delivery extends Thread {
 Mailbox m;
  int book;
  Delivery(Mailbox mm, int b) {
     m = mm; book = b;
  }
 public void run() {
    try { sleep(1000); }
    catch (InterruptedException e) {}
    synchronized (m) {
      m.receive_book(book);
      m.notifyAll();
   }
 }
}
```

## The multi-book problem

```
class BookOrder extends Thread {
  int book;
  Mailbox m:
  BookOrder(Mailbox mm, int b) { m = mm; book = b; }
 public void run() {
    System.out.println("Ordering book " +
                Integer.toString(book) );
    Thread t = new Delivery(m, book);
    t.start();
    synchronized (m) {
      while (m.which_book() != book) {
        try { m.wait(); }
        catch (InterruptedException e) {}
      }
    }
    System.out.println("Book " +
     Integer.toString(book) + " Arrived");
 }
}
```

# The multi-book problem

Finally, the main routine kicks off two ordering threads.

▲□▶▲□▶▲□▶▲□▶ □ のQの

```
public class MultiOrder {
   static Mailbox m = new Mailbox();
   public static void main(String args[]) {
     BookOrder t1 = new BookOrder(m, 1);
     BookOrder t2 = new BookOrder(m, 2);
     t1.start();
   t2.start();
   }
}
```

Last solution relied on threads to synchronize their own access to the Mailbox. Mailbox should be doing this itself:

    while (book != b) {
      try { wait(); }
      catch (InterruptedException e) {}
 }
}
```

```
class Delivery extends Thread {
 Mailbox m;
  int book;
 Delivery(Mailbox mm, int b) {
   m = mm; book = b;
  }
 public void run() {

# Summary of Java's Concurrency Support

- Thread-based shared memory model
   Fundamentally nondeterministic; correctness the resposibility of the programmer
- Per-object locks can ensure atomic access
   Choice of locks by convention, although there is often a natural choice. Danger of deadlock.
- Wait/notify mechanism for synchronizing threads Undisciplined use can lead to races and deadlocks, but following a pattern avoids most problems.
