# Introduction

## Background && Goals

Current equation solving languages, such as R, Matlab, Mathematica, though powerful, still require users to have a basic understanding for programming. It is hard for young students in high school or college with no programming background to start using programming to solve the calculations from homework and textbooks. However, programming is extremely helpful when they have multiple variables and tens of equations when manually calculation is time consuming and error prone. Therefore, we truly think it will be great if we can create a

programming language that helps students solve tedious and lengthy mathematical equations with very simple and flexible syntax. Our language EqualEqual targets to be an educational tool for students so that students can move their equations on their whiteboard to a EqualEqual program with as little change as possible. We believe that using programming to solve questions should not be an obstacle for students in their studies, and thus have students enjoyed more with their studies.

## Language Evolution

EqualsEquals - "eqeq" for short - is a language designed for simple equation evaluation. EqualsEquals helps express mathematical equation in ASCII (though UTF-8 string literals are allowed) without straying too far from whiteboard-style notation. Users do not need to be overly careful to perfectly reduce formulas behind. Leaving unknowns for later is possible, without encapsulating equations' unknowns as function parameters. EqualsEquals takes multiple equations as input and can evaluate the value of a certain variables of the equations when the values of other variables are given.

# Tutorial

## Environment Setup

The compiler has been built and tested on OS X El Capitan, Ubuntu 15.10. The EqEq compiler Installation of Dependencies below:

### **Installation under Ubuntu 15.10**

```
$ sudo apt-get install -y ocaml m4 opam  
$ opam init  
$ eval `opam config env`
```

### **Installation under OS X**

```
$ brew install opam  
$ opam init  
$ eval `opam config env`
```

After OPAM is initialized, go to the the directory where you want EqEq installed and clone the git repository:

```
$ git clone https://github.com/rxie25/PLT2016Spring.git
```

## Using the Compiler

Inside the directory of the cloned file

```
$ cd src  
$ make
```

This creates the complier for EqEq that takes in '.eq' files and complies them to corresponding '.c' files as C code files. To run Eqeq executable is:

```
$ ./eqeq.native [options] < [your file name]
```

There are additional flags `-s` for printing the dependency table of the variables.

# Basics and Syntax

## Primitives

All primitive are declared with implicit types by an identification.

## Operators

EqEq supports the following operators:

1. Arithmetic: +, -, /, \*, ^, %, sin, cos, tan, sqrt, log, | ID |  
eg.

```
SomeCtx = {  
    a = -42;  
    b = | a |; /* the value of b is 42 */  
    c = 2^2; /* the value of c is 4 */  
}
```

2. Conditional: ==, !=, <, <=, >, >=, &&, ||, !

3. Other: range

```
range(3);           // same as writing: {0, 1, 2, 3}  
range(-3);         // same as writing: {0, -1, -2, -3}  
range(2, 5);       // same as writing: {2, 3, 4, 5}  
range(8, 2, -3);   // same as writing: {8, 5, 2}
```

## Control Structures

The statements inside source files are generally executed from top to bottom according to the appearance of `Find` blocks.

The execution order of multi-equations inside the `Context` blocks are determined and recomputed each time when one of the multi-equations inside the `Context` blocks changes. The order is determined by DFS with starting vertex of the current changed variable on the acyclic variable graph. The acyclic variable graph is stored as an adjacency list format that record the dependencies of each variable. A DFS is used to detect whether there is a cycle in the graph. If there is a cycle in the graph, an error will be raised, eg. `Cyclical dependency`.

Inside each multi-equation, the control flow statements break up the flow of execution by decision making statements (if-else, if-else if-else), looping statements (range, while) and branching statements (break, continue, return).

## Decision Making

```

SomeContext = {
    a = { 42.333; }
}

SomeContext:find a {
    if (1) {
        a = 22;
    } else {
        a = 233;
    }
    /* a is now 22 */

    if (0) {
        a = 22;
    } else {
        a = 233;
    }
    /* a is now 233 */

    if (3>4){
        a = 3;
    }
    else if (4>3){
        a = 4;
        print("%.0f\n", a);
        /* the value of a is 4 */
    }
    else if (4>3){
        a = 4;
    }
    else{
        a =0;
    }
    print("%.0f\n", a);
    /* the value of a is 4 */
}

```

## Loops

```

Foo = {
    a = 1;
    b = 3;
}

Foo: find a {
    while (a < 3) {
        print("%.0f\n", a);
        a = 3;
        /* the value of a = 3 now */
    }
}
/* it will print 1. */

Foo: find a with b in range(2); {

```

```
    print("a+b = %.0f\n", a + b);
}
/* the output will be 1, 2, 3 on separate lines. */
```

## Branching

```
SomeContext = {
    a= 1;
}
SomeContext: find a{
    while(a<3) {
        break;
        a = 2;
    }
    /* the value of a is still 1. */

    while(a<4) {
        print("%.0f\n",a);
        a=a+1;
        continue;
        print("%.0f\n",a);
    }
    /* it will print 1, 2, 3 on separate lines. */
    /* the value of a now is 0. */
}
```

# Example Programs

## Definition of a Program

The simplest - though contrived - valid program is:

```
a = 42;  
find a { printf("Hello, all %.0f readers!\n", a); }
```

Which prints the following to standard out: Hello, all 42 readers!

Formally, a valid program is a series of:

- one or more `find` blocks.
- zero or more "context" blocks (*aside from the automatic, global context*)

## "Context"s & `find` Blocks

While both types of blocks of code are simply curly brace enclosed listings of sequential statements, contexts and `find` blocks differ in their use:

- `contexts` are expected to layout and define equations for use later.  
Thus they're allowed semantic gaps in their equations; eg: missing solutions.
- `find` blocks on the other hand are expected to be the resolution to "find"  
missing said pieces, or simply apply completed solutions to new inputs.

The `context` block consists of a list of single line and/or multi-line equations.  
The single line equations is expressed in assignment format.

```
SomeCtx = { a = 42; }
```

Multi-line equations, like single line equations, must be expressed in assignment format, but right hand side is express in `{*... multi-line statements ...*}`. In this case right hand side variable is treated as a variable. However nested `{}{}` is considered illegal in eeqq.

```
Multi = {  
    // multi-line equation life  
    life = {  
        if (a == 42) {  
            a;  
        } else {  
            17;  
        }  
    }  
}
```

```

        }
    }

Multi: find life {
    a = 42;
    print("%.0f\n", life);
    /* prints out 42 */
}

```

It follows then that `find` expressions *apply* to contexts. Where a context might be shared for re-use, `find` expressions are designed to make local use of equations in a given context.

Though the above "Hello World" example executes a `find` on the global context, users will generally define contexts manually. For example a "Euclid" context, where `gcd` might be defined:

```

Euclid = { gcd = /*... defined here ...*/; }
Euclid: find gcd {
    a = 20; b = 10; print("%.0f\n", gcd);
}

```

## Sample program

Below are example programs in EqualsEquals.

### Example of Equations' `find` Use-cases

```

sum = 0; // initialize a number called sum
Pendulum = {
    /**
     * Spell out equation for our compiler:
     *   m * g * h = m * v^2 / 2
     */
    m = 10;
    theta = pi / 2;
    g = 9.8;
    h = 1 - l * cos(theta); // cosine, being a built-in
    v = (2 * g * h) ^ (1 / 2); // square root
    // note: relying on existing libraries for cos
}

// evaluate v in pendulum's equations given that g = 9.8 and l in range(20)
Pendulum: find v with l in range(0, 20) {
    // Our compiler now has solutions to: m, g, l (and indirectly h), so v can
    // be solved:

    print("velocity: %f", v);

    // v is automatically evaluated when it's referred to
}

```

```

}

// evaluate v in pendulum's equations given that g in range(4, 15) and l = 10
// take the average of values of v
Pendulum: find v with m = 100; g in range(4, 15); {
    l = 10;
    sum += v;
    // scope of sum: global (b/c it's not in the scope of pendulum but would be
    // overwritten by pendulum)
}

Pendulum: find v with v in range(20); {
    // throw a compiler error because can't find v with v's value
}

// Example: tries l = 10, v = 20 in context of pendulum, to see its equations
// are still true. If equations are inconsistent, the program will throw an
// exception.
Pendulum: find v {
    l = 10; // by now, v will be calculated
    print("%.0f", v == 20); // print 1
    v = 20; // throws an error
}

```

## Example of a multi-line equation to find `gcd` of `a` and `b`

```

Gcd = {
    gcd = {
        a= 10;
        b=20;
        while (a != b) {
            if (a > b) {a = a - b;}
            else {b = b - a;}
        }
        a; /* returns a back to gcd*/
    }
}

Gcd:find gcd {
/* evaluate gcd of 10 and 20 */
    a = 10;
    b = 20;
    print("gcd of %.0f and %.0f is %.0f\n", a, b, gcd);
}
/* END: Example of a multi-line equations to find gcd of a and b */

/* This works too. In this case, gcd is not in any special scope */
a = 1, b = 2;

// evaluate gcd of 10 and 20
find a {
    a = 10;
    print("a = %.0f and b = %.0f\n", a, b);
    /* print a = 10 and b = 2 */
}

```

```
}
```

```
/* END: Example of a multi-line equations to find gcd of a and b */
```

# Reference Manual

## Introduction

EqualsEquals - "eqeq" for short - is a language designed for simple equation evaluation. EqualsEquals helps express mathematical equation in ASCII (though UTF-8 string literals are allowed) without straying too far from whiteboard-style notation. Users do not need to be overly careful to perfectly reduce formulas behind. Leaving unknowns for later is possible, without encapsulating equations' unknowns as function parameters. EqualsEquals takes multiple equations as input and can evaluate the value of a certain variables of the equations when the values of other variables are given.

## Motivation

Reducing mathematical formulas can be really painful and tedious. We want to simplify the process of evaluating equations. With our language we take a step to help users leave their formula in a similar format to what they'd normally have on paper.

## Overview

Valid source programs will compile down to C.

## Definition of a Program

The simplest - though contrived - valid program is:

```
find { printf("Hello, all %.0f readers!\n", 21 * 2); }
```

Which prints the following to standard out: Hello, all 42 readers!

Formally, a valid program is a series of:

- one or more `find` blocks.
- zero or more "context" blocks (*aside from the automatic, global context*)

## "Context"s & `find` Blocks

While both types of blocks of code are simply curly brace enclosed listings of sequential statements, contexts and `find` blocks differ in their use:

- **contexts** are expected to layout and define equations for use later.  
Thus they're allowed semantic gaps in their equations; eg: missing solutions.
- **find** blocks on the other hand are expected to be the resolution to "find"  
missing said pieces, or simply apply completed solutions to new inputs.

The `context` block consists of a list of single line and/or multi-line equations.  
The single line equations is expressed in assignment format.

```
SomeCtx = { a = 42; }
```

Multi-line equations, like single line equations, must be expressed in assignment format, but right hand side is express in `(*... multi-line statements ...*)`. In this case right hand side variable is treated as a variable. However nested `{}{}` is considered illegal in equeq.

```
multi:{  
    // multi-line equation life  
    life = {  
        if (a == 42) {  
            a;  
        } else {  
            17;  
        }  
    }  
}  
  
multi: find life {  
    a = 42;  
    print("%.0f\n", life);  
    //prints out 42  
}
```

It follows then that `find` expressions *apply* to contexts. Where a context might be shared for re-use, `find` expressions are designed to make local use of equations in a given context.

Though the above "Hello World" example executes a `find` on the global context, users will generally define contexts manually. For example a "Euclid" context, where `gcd` might be defined:

```
Euclid = { gcd = /*... defined here ...*/; }  
Euclid:find gcd {  
    a = 20; b = 10; print("%.0f\n", gcd);  
}
```

## Design Implementation

Within contexts and `find` blocks, valid statements look like many C-style

languages, where expressions are semi-colon (;) separated, may be have sub-expressions using parenthesis ((, )) and the lexemes of an expression may be made up of:

1. **variables** to which floating-point numbers are assigned
2. **arithmetic** expressions: addition, subtraction, multiplication, division, exponents
3. **comments** characters ignored by the compiler
4. **white-space** to arbitrary length (eg: `a = 3` is the same as `a = 3`)
5. **string** literals used for printing
6. **equality** operations in `if/else` expressions (*which evaluate to 1 or 0 if both operators are equal*)

## Tokens: Expressions' Lexemes

Below is the syntax of each type of expression. For the semantic description of each, refer to the "[Declarations](#)" section, below.

1. Floating point numbers, including integers:

`eg: 123, 1.34e-4, 0.23, .13, 0e1.`

Described by the regular expression `flt` here:

```
let pos = ['1' - '9']          in
let dig = '0' | pos           in
let exp = ('e' | 'E') ('-' | '+')? pos+ in
let fra = '.' dig+ exp?     in
let num = pos dig*           in

let flt = num | ((num | 0)? fra) | (num exp)
```

2. Variable Assignment: numbers stored with user-defined names:

`eg: weight = 100 /*grams*/`

Described by the regular expression `var` here:

```
let aph = ['a'-'z'] | ['A'-'Z']      in
let var = aph+ ('_ | ['0'-'9'])*
```

3. Contexts: blocks of symbols:

`eg: Euclid: {/* any number of lines of EqualsEquals here */}`

Building on variables' definition, the regular expression can be described by `ctx` here:

```
let ctx = ['A'-'Z'] var*
```

#### 4. Strings: mostly used for printing results:

eg: `printf("result of my maths: %.0f\n", gcd)`

String literals can be described by the regular expression `str` here:

```
let chr = \x(0...9|A...F|a...f)(0...9|A...F|a...f) in
let spc = \(\n| \t| \b| \r| ' ')
let num = ['0' - '9']                      in
let aph = ['a' - 'z'] | ['A' - 'Z']        in

let str = (aph | num | chr | spc)*
```

## Reserved Keywords

Following are reserved keywords, and have special meaning in the language. See "Statements" and "Declarations" sections elsewhere for each of their meanings.

- `if`
- `elif`
- `else`
- `find`
- `print`
- `Global`

Eeq is translated into C, so it has the same set of reserved keyword as in C in addition to the reserved keywords above.

- `int`
- `double`
- `char`
- `float`
- `const`
- `void`
- `short`
- `struct`
- `long`
- `return`
- `static`
- `switch`
- `case`
- `default`
- `for`
- `do`
- `goto`
- `auto`
- `signed`
- `extern`
- `register`
- `enum`
- `sizeof`
- `typedef`

- `union`
- `volatile`

## Declarations

1. A list of declarator are separated by comma. Formatted as below:

```
Declarator-list:
declarator, declarator, ...
```

For example:

```
a = 2, b = 3;
a = b, b = a % b;
```

2. Variable:

To declare a variable, only name of the variable is needed. The data types of the variables are inheritable.

Possible inherited data types:

- `Double`
- `String`

3. Multi-line equation: declaration of multi-line equation has the format:

```
equation_name = {
    // some operations
    var; // a variable, indicating equation_name's value
}
```

The `equation_name` has the type `Double`, where `var` indicates the name of variable expression holding the desired value. The equation will be passed by value. The multi-line equations, like regular equations, can only express one value.

For example:

```
gcd = {
    if (0 == b) {
        a; // solution is a
    } elif (a == 0) {
        b; // solution is b
    }

    if (a > b) {
        a = b, b = a % b;
        // note: multiple assignments on single line
    }
}
```

```

} else {
    a = b % a, b = a;
}
gcd; // solution is gcd w/the current a and b
}

```

This example results in an expression `gcd` - similar to a C-style function - that can be referred to later, given the necessary inputs `a` and `b` (in `eqlq's` case, the right "context").

#### 4. Equations:

```

variable = variable (value assigned?)
variable = some arithmetic expression
variable = { /*some multi-line equation that evaluates to a number*/ }

```

Only `variable` will be allowed on the left side of the equal sign. The expression on the right side can be a declared variable, an arithmetic expression that evaluates to a number, or a multi-line equation enclosed in curly-braces (see "Multi-line equation" above).

For example:

```

a = 3; b = a;           // b == 3
a = 3; b = a * 2 + 1;  // b == 7
a = 3; b = 6; c = gcd; // c == 3

```

For analysis of equation arithmetic, see "Expression Precedence & Meaning", below.

#### 5. Scopes (access to variables):

```

VAR = EXPR;

Scope_name {
    list of equations

    // VAR = EXPR // overwrites global `VAR`
}

Scope_name: find VAR [with VAR_B in range()*] {
    /** code here has access to `Scope_name`'s equations */
}

```

Here, `Scope_name` is like an object of equations. Equations are put inside the bracket follow `Scope_name`.

Any variable declared outside of a `Scope_name` is a global variable that can be accessed from anywhere within the program. It can evaluate any variable in the global context and overwrite the expressions in the global context. If a variable declared in some `Scope_name` has the same

name as some global variable, it will overwrite the value within the `Scope_name`. After getting out of the `Scope_name`, the variable will restore its value.

`Scope_name: find VAR [...]` is the evaluation part. A `with` clause is optional. See "With Statement" section below. `find` will evaluate the variable following it using the equations inside the `Scope_name` block. Once a `Scope_name` is defined, multiple `find` are allowed to use the equations inside it.

## Statements

### Expression Statement

Expression statements are statement that includes an expression and a semicolon at the end:

```
expression ;
```

### Combining Statements

A statement can be the multiple of other statements. `{` and `}` are used to group multiple statements as one statement. So the form of compound statements is:

```
{ statement+ }
```

, which means that a compound statement has an opening curly bracket, one or more statements, and a closing curly bracket.

### Conditional Statement

Statements that are used in conditional statements:

```
// if_statement  
if ( expression ) statement  
  
// elif_statement  
elif ( expression ) statement  
  
// else_statement  
else statement
```

Conditional statements have the following form:

```
if_statement elif_statement* else_statement?
```

, which means that it contains a required `if_statement`, any number of `elif_statement`, and an optional `else_statement`.

## **While Statement**

While statements have the form:

```
while ( expression ) statement
```

The sub-statement is executed repeatedly so long as the value of the expression remains non-zero.

## **Break Statement**

The statement

```
break ;
```

causes termination of the smallest enclosing `while`, or `with` statement.

## **Continue Statement**

The statement

```
continue ;
```

causes control to pass to the loop-continuation portion of the smallest enclosing `while` or `with` statement; that is to the end of the loop. More precisely, in each of the statements.

## **Context statement**

A context statement include a context name and a compound statement:

```
context_name compound_statement
```

To access a context, we use a statement with the following form:

```
context_name: statement
```

The sub-statement will be evaluated in the context given by `context_name`.

Examples:

```
mycontext {
    x = 5;
}
```

```
print(x); // throw an exception because x is not defined
mycontext: find x {
    print(x); // prints 5
}
```

## With Statement

With statements have the form

```
with [variable in expression; ]+ compound_statement
```

, which means that with takes one or more expressions, and a compound sub-statement. (After each expression, a semicolon is needed after the expression.)

If the expressions have type double, then with will evaluate the expression and execute the compound sub-statement:

```
with x = 5; {
    print(x);
} // 5

with x = 5; y = 6; {
    print(x + y);
} // 11
```

## Find Statement

Find statements start with keyword `find` and an expression, followed by a sub-statement:

```
find expression statement
```

In a find statement, the last statement should be evaluated with access to previously declared expressions.

Examples of find statements:

```
// a simple example
velocity = length + 1;

find velocity {
    length = 5;
    print(velocity);
} // print 6

// this block is the same as the one above
find velocity with length = 5; {
    print(velocity);
```

```
    } // print 6

pendulum:find vector with length in range(0, 5); {
    print(velocity);
} // print 1 to 6
```

### range()

`range()` mimics Python's `range()` function. It takes an optional expression `start`, an expression `stop`, and an optional expression `step`. It returns a vector from `start` to `stop - 1`, with distance `step` between each member of the vector:

```
range([start,] stop [,step]);
```

For examples,

```
range(3);           // same as writing: {0, 1, 2, 3}
range(-3);          // same as writing: {0, -1, -2, -3}
range(2, 5);        // same as writing: {2, 3, 4, 5}
range(2, 8, 3);    // same as writing: {2, 5, 8}
```

Range has to be the last argument in the find block.

For examples,

```
SomeCtx: find a with b = 3; c in range(3); {} // correct syntax
SomeCtx: find a with c in range(3); b = 3; {} // illegal syntax
```

## Built-ins

### print()

`print()` is built-in function that mirrors the C `printf()` API. `print()`'s arguments include a string, and optional expressions:

```
print( a_string_with_formatters [, expressions]* )
```

`print()` prints the formatted string to the screen.

Users can format strings in `print()` with `%f` and `%s` formatter (and but not `%d`, since `eqeq` only uses float). For example,

```
print("words here %f.0 and %f here\n", 4, myvar);
// words here 4 and 3.14159 here
```

Unlike the built-in functions below print function does not support any unary or binary operators.

```
-print("words here %f.0 and %f here\n", 4, myvar);
// will throw the following error
Fatal error: exception Failure("Illegal use of operator on print, \"-\"")
```

**sin()**/**cos()**/**tan()**/**sqrt()**/**log()**

**sin()**/**cos()**/**tan()**/**sqrt()**/**log()** are built-in trigonometry and math functions that mirrors the same functions in C under `math.h` library. Their arguments include variable names and numbers only. Nested built-in functions are allowed.

Numerical range for `sqrt()`/`log()` and is confined to greater or equals to zero and greater than zero respectively and are checked statically at compile time. Like most imperative language illegal argument for the above built-in functions cannot be caught at compile time for variables, will will be reported at C runtime.

```
a = cos(sin(tan(log(sqrt(42)))));
```

functions can be nested like the example above.

## Expression Precedence & Meaning

Here various expressions' meanings are described, generally shown as `expr`, in the order of their precedence.

- `'(' expr ')'`: for sub-expressions. For example, `expr` of `4 + 5` here:

```
b * (4 + 5); // `expr` should be considered first
b * 9;        // same as above; note absence of parenthesis
```

- `-expr`: negative. The result is the negative of the expression. Note, the type of the expression must be double.
- `!expr`: logical negation.

The result of the logical negation operator `!` is `1` if the value of `expr` is `0`. If the value of `expr` is anything other than `0`, then `!expr` results in `0`.

- `left_expr ^ right_expr`: exponentiation. Mathematically raises `left_expr` to the power, `right_expr`. Note: uses underlying C standard library's corresponding power API, eg: `double pow (double base, double power)`.
- `expr * expr, expr / expr` The binary operator `*` / indicates multiplication and division operation. If both operands are double, the result is double.
- `expr % expr` The binary `%` operator yields the remainder from the division

of the first expression by the second. Both operands are double, and only integer portion of the double will be used for modular operation, and the result is a double with fraction equals to zero. eg:

```
12.0 % 7.0 = 5.0;
12.3 % 7.5 = 5.0;
```

- `expr + expr, expr - expr` The result is the sum or different of the expressions. Both are double, the result is double.
- equality/inequality:
  - `expr > expr, expr >= expr, expr < expr, expr <= expr` The operators < (less than), > (greater than), <= (less than or equal to) and >= (greater than or equal to) all yield 0 if the specified relation is false and 1 if it is true. Operand conversion is exactly the same as for the `+` operator.
  - `expr != expr, expr == expr`: The `!=` (not equal to) and the `==` (equal to) operators are exactly analogous to the relational operators except for their lower precedence. (Thus `a < b == c < d` is 1 whenever `a < b` and `c < d` have the same truth-value).
- `expr || expr` The `||` operator returns 1 if either of its operands is non-zero, and 0 otherwise. It guarantees left-to-right evaluation; moreover, the second operand is not evaluated if the value of the first operand is non-zero.
- `expr && expr` The `&&` operator returns 1 if both of its operands is non-zero, and 0 if either is 0. It guarantees left-to-right evaluation; moreover, the second operand is not evaluated if the value of the first operand is 0.
- `left_expr = right_expr`: assignment. the `left_expr` must be a single variable expression. The result of this operation is that `left_expr` holds the value of `right_expr` going forward. If `right_expr` contains unknown variables, the `left_expr` will not be solvable until a `find` block expresses a solution in terms of `left_expr` and provides any missing variables from the `right_expr`.
- `expression , expression` A pair of expressions separated by a comma is evaluated left-to-right and the value of the left expression is discarded. The type and value of the result are the type and value of the right operand.

## Sample program

Below are example programs in EqualsEquals.

### Example of equations' `find` Use-cases

```

sum = 0 // initialize a number called sum
pendulum {
    /**
     * Spell out equation for our compiler:
     * m * g * h = m * v^2 / 2
     */
    m = 10;
    theta = pi / 2;
    g = 9.8;
    h = l - l * cos(theta); // cosine, being a built-in
    v = (2 * g * h) ^ (1 / 2); // square root
    // note: relying on existing libraries for cos
}

// evaluate v in pendulum's equations given that g = 9.8 and l in range(20)
pendulum: find v with l in range(0, 20) {
    // Our compiler now has solutions to: m, g, l (and indirectly h), so v can
    // be solved:

    print("velocity: %f", v);

    // v is automatically evaluated when it's referred to
}

// evaluate v in pendulum's equations given that g in range(4, 15) and l = 10
// take the average of values of v
pendulum: find v with m = 100; g in range(4, 15); {
    l = 10;

    sum += v;
    // scope of sum: global (b/c it's not in the scope of pendulum but would be
    // overwritten by pendulum)
}

average = sum / (15 - 4);

pendulum: find v with v in range(20); {
    // throw a compiler error because can't find v with v's value
}

// Example: tries l = 10, v = 20 in context of pendulum, to see its equations
// are still true. If equations are inconsistent, the program will throw an
// exception.
pendulum: find v {
    l = 10; // by now, v will be calculated
    print(v == 20); // print 1
    v = 20; // throws an error
}

```

## Example of a multi-line equation to find $\text{gcd}$ of $a$ and $b$

```

Gcd = {
    gcd = {
        a= 10;

```

```

b=20;
while (a != b) {
    if (a > b) {a = a - b;}
    else {b = b - a;}
}
a; /* returns a back to gcd*/
}

Gcd:find gcd {
/* evaluate gcd of 10 and 20 */
a = 10;
b = 20;
print("gcd of %.0f and %.0f is %.0f\n", a, b, gcd);
}
/* END: Example of a multi-line equations to find gcd of a and b */

/* This works too. In this case, gcd is not in any special scope */
gcd = {
    ... // same as the above example
}

// evaluate gcd of 10 and 20
find gcd {
    a = 10;
    b = 20;
    print("gcd of %.0f and %.0f is %.0f\n", a, b, gcd);
}
/* END: Example of a multi-line equations to find gcd of a and b */

```

# Project Plan

## Roles and Responsibilities

We assigned four main roles Manager, Language Guru, System Architect, Testers to each member on the team. As we developed our language, the role were not that clearly divided. The team would help each other when we ran into particularly difficult problems, and assign each other pull request to review before merge. The table below illustrates the main roles and one example of a part we contributed heavily in.

Name	Responsibilities
Nam Hoang	Language Guru, Code Generation
Tianci Zhong	Manager, Semantic Analysis, Code Generation
Ruicong Xie	Tester, Semantic Analysis
Lanting He	Tester, Code Generation
Jonathan Zacs	System Architect, Semantic Analysis

## Timeline

Time	Events
Jan 25	First Commit
Jan 25	Submitted Project Proposal
Mar 7	Submitted Language Reference Manual
Mar 27	First Travis CI Build
Mar 31	Successfully Generated Code (“Hello World”)
April 25	Major Language Features Complete
May 7	Variable Dependency Resolved
May 9	Presentation Presentation

## Specification

At the beginning of the semester we had the idea to make a physics language. Later we realized a lot of the problem we have to solve are just mathematical equations. That's when we had the idea to make EqEq, a mathematical language that solves equations. However we later found symbolic mathematical manipulate was too broad of a topic to tackle, so we scaled our compiler back to variable resolution in mathematical equation.

## Development

We first worked together on `scanner.mll`, `parser.mly` and `ast.ml`, as no one on our team had any prior experience with OCaml. Our first milestone was to make a very basic scanner, parser, and generator. We built up the basic pipeline for automated testing on Travis CI. Whenever we worked on a new feature, we would create a new branch and open a pull request to merge with master. No pull request was accepted unless it passed all of the tests and was reviewed by one of the team member. Once we had simple hard coded version of `hell-world.eq` working with our compiler, we quickly decided to split into smaller groups to tackle some more difficult problems, like multiple-line equation, context resolution, variable dependency, etc. We initially added semantic analysis and naive version of variable mapping for scope and variable resolution. However we soon realized the the problem is more complex, and built `relation.ml` a variable dependency table to deal with the problem, in which we used DFS to detect cyclic reference.

## Testing

While developing the code, we concurrently tested what we wrote. When we initially developing our language we had `debugtokenizer.ml` and `debug_frontend.py` to test the front end of our language. The first program splits out correct recognized tokens when fed with source code in eqeq, while the second one runs the tokens through `parser.ml` with `menhir`. After we finished the bulk of the front end of our compiler. We set up automated testing on Travis CI with `.travis.yml` to test if our language is compiling properly for each commit. All the testing suite and processes will be discussed in detail later in the testing section of this report.

## Software Development Environment

### Programming Language Stack

- Git Repository Hosted on Github for version control which contains the compiler code and test suite
- OCaml for scanning, parsing, and semantically checking eqeq source code and generation of C target code output
- Bash Shell Scripts for running our program given an input eqeq file (.eqeq) and an output C file (.c) file, as well as automating testing

- Makefile for all things compiling, linking, and test related

## Tools

- Travis CI for automated continuous integration testing through Github to make sure no new code modifies the correct functionality of the language
- Sublime, Atom, Vim for text editing, depending on each team member's preference

## Programming Style Guide

While programming, all group members followed these following style guidelines to ensure our project stayed consistent:

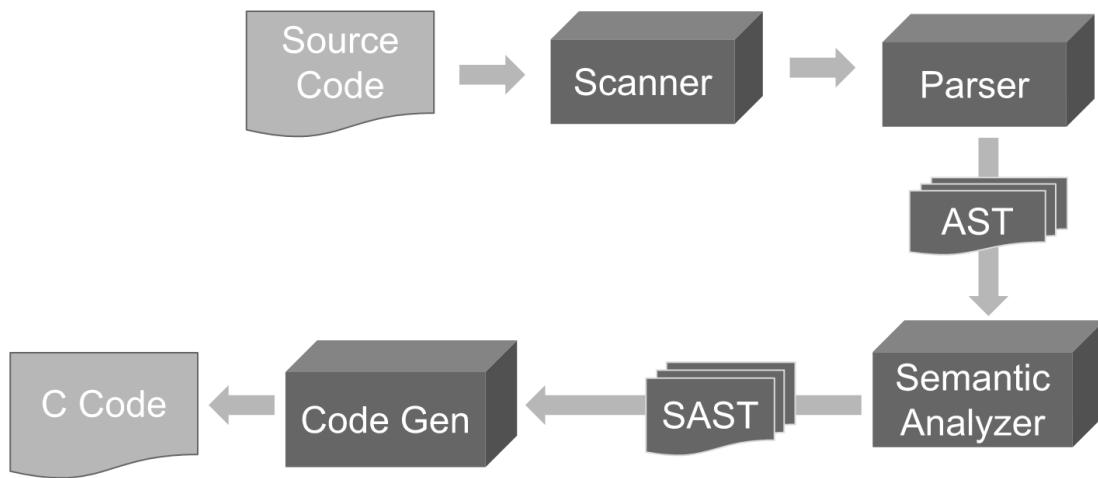

- Lines of code should not be more than 80 characters
- No tabs for indentation
- Indentation is always 4 spaces
- Naming consistency between the different program files
- Newline at the end of each file
- One line between each declaration block
- White space for readability

# Translator Architecture

The compiler is, of course, built in OCaml. The architecture of the compiler is demonstrated in the block diagram below. Our compiler source code includes 8 files:

- `egeq.ml` - main module that calls other modules to produce the output
- `ast.ml` - AST (abstract syntax tree) representation of the language
- `sast.ml` - SAST (semantically checked AST) representation of the language
- `scanner.ml` - tokenizes a source file
- `parser.ml` - constructs an AST from the output tokens of the scanner
- `semant.ml` - checks the incoming AST to make sure that the AST is semantically correct, and produces a SAST
- `relation.ml` - an extension of `semant.ml`, used to generate a large part of the SAST
- `codegen.ml` - converts a SAST into a working C code

## Compiler Architecture

In summary, the source code is passed through the scanner and parser to create an Abstract Syntax Tree, which then went through the Semantic Analyzer to create a modified AST (aka. SAST). The C code is generated from the SAST using a code generator.

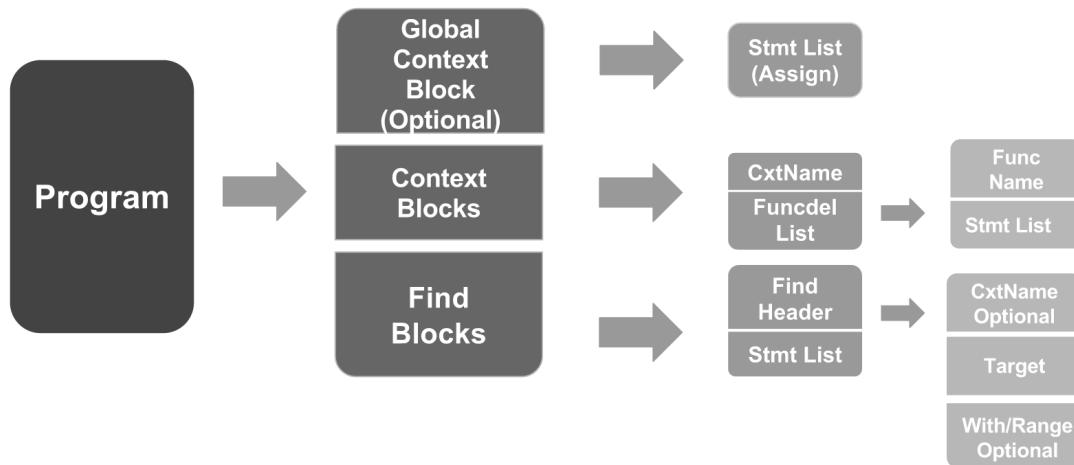

## Scanner

The scanner tokenizes the input from the input file. Additionally, it discards unnecessary characters and check the syntax of the program.

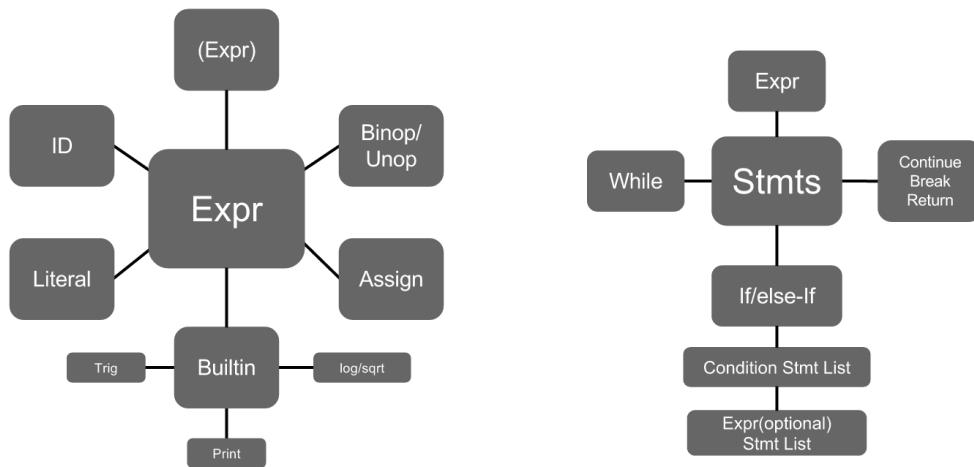

## Parser

The parser constructs an abstract syntax tree (AST) with the input token from the scanner. The highest level of the AST contains a global context block, all context blocks and all find blocks. The following figure demonstrates the main structure of the AST. The parser also further checks the syntax of the program. The combination of the parser and the scanner makes sure that the input program is syntactically correct.

## Parser

## AST

## Semantic Analyzer

The semantic analyzer has two main jobs. The first one is to check for all the semantic errors of the program. The following semantic errors are checked in our compiler:

- Illegal usage of reserved keyword, e.g: break
- Illegal usage of duplicate context block
- Illegal usage of mathematical equation, e.g: cos(3,4,5)
- Lower case Context name
- Bad syntax of if / if-elseif /if-else
- Undeclared variables and undeclared context
- Illegal use of build-in function (e.g: print("%0.0f ", a)-print("%0.0f ", a); range(3, 5, "abc"))
- Illegal return
- Illegal find block declaration
- Cyclic dependency

The second job of the semantic analyzer is taking the parser's AST and producing an SAST. Our SAST contains the AST, a multi-line equation dependency structure, a context variable map, and a library list.

- **Multi-line equation dependency structure** - At the high level, the multi-line equation dependency structure can be understood as a structure of graphs where each node is a variable, and each edge is the dependency between two variables. The multi-line equation dependency structure contains all the variables that are declared for each context block and its corresponding find blocks. The structure indicates whether a variable is dependent on other variables or not. If a variable  $x$  is independent of other variables, the structure shows the expression assigned to  $x$ . If a variable  $y$  is independent of other variables, the structure shows the list of variables that  $y$  depends on.
- **Context variable map** - This is a structure that contains information of the variables for each context. The generator uses the information provided by the context variable map to generate definitions for variables (e.g. "double x;") and to match the name of the variables with the corresponding names in the generated code in C (e.g. a variable  $a$  in context `MyCtx` could be named as `MyCtx_a_<counter_number_to_avoid_duplicates>`).
- **Library list** - This is a list of strings that contains everything in the running EqualEqual program that calls C library functions ( e.g: `cos()` will call `math.h` and `print()` will call `stdio.h` ). In `Codegen.ml` we will scan through this list and include the corresponding C libraries in the generated C code.

## Code Generator

The code generator uses the SAST provided by the semantic analyzer to construct the `c` instructions for the `eqlqq` program.

- **Global context and context blocks** - Multi-line equations in both global context and context blocks are generated as functions in the output C program. The return value of a function will be the result of the multi-line equation. To be unique, a function name includes the corresponding context name and a counter (e.g. `MyCtx_a_0()`).
- **Find blocks** - Find blocks are generated as a function in the output C program (e.g. `find_MyCtx_1()`). In find blocks, variables that are defined and used locally will be assigned to the corresponding functions in global context (e.g. `a = MyCtx_a_0(b, d);`).
- **Dependency Generation** - The multi-line equations are resolved when a new variable is declared. The functions needed to be regenerated will be generated using the multi-line equation dependency structure, as mentioned in the above section (Semantic Analyzer). Since efficiency is not a priority, the dependency generation might generate duplicated assignments.
- **Range** - Range function are generated by wrapping around the generated find function with a outside for loop function

```
SomeCtx:find a with b = 10; c in range(0,2);{
    .....
}
```

```
void find_SomeCtx_0_range() {
    double c;
    for(c=0.000000; c<=3.000000; c=c+1.000000) {
        find_SomeCtx_0(c);
    }
}
```

## Utilities

The compiler can generate pretty-print strings for AST and SAST with flags `-a` and `-s`. The printed AST and SAST show us the output of the program through different phases and help debugging much faster.

# Test Plan

EqEq compiler has had *passing* end-to-end tests from the [start](#) - from the moment a basic "hello world" was compiling.

## Test Strategies: `make e2e`

Our compiler uses two types of test-coverage: the main tests via `make test` and extraneous tests, via `make lint`

1. `make test`: this runs every `tests/{test,fail}-*.eq` file through the compiler - `eqeq.native` - and for each:

test file	<code>eqeq.native</code>	exit status	compared outputs
-----	-----	-----	-----
test-NAME.eq	0 (zero)	resulting target program output matches	<code>test-NAME.out</code> golden sample
fail-NAME.eq	!= 0 (non-zero)	<code>./eqeq.native</code> error matches	<code>fail-NAME.err</code> golden sample

2. `make lint`: anything general to *building* our compiler

eg: early on, this ensured our scanner/parser phase didn't produce shift-reduce warnings (*at one point, accidentally ignored*)

## Policy: Changes Must be Tested

Each change to the compiler - feature or bug-fix - was explicitly required to be committed with a **new** test file before being merged into `master`. In fact, the [official recommended steps to work on the compiler](#) states:

before creating [your new change] write tests for it [and] **ensure it FAILs**

When developing, members relied on `make test`'s report to look for their new test's red or green "FAIL"/"PASS" indicator. This single testing command (`make test`) ran all of the compiler's existing tests as well. The benefit of this approach was that, other team members could focus solely on their own feature's side-effect and get immediate, unsolicited feedback in the event of an inadvertent regression.

## Automation: `master` Must Pass

The compiler's github codebase is configured to send each `master` commit (including merges) to the popular automated test [runner travis-ci.org](#) for a `make e2e` run. This means we all knew immediately if someone made a mistake and merged their in-progress work from an experimental branch, into `master`, before it was ready. This came in handy more than once, where we were able to simply revert the offending merge and get `master` passing again (*facilitating others to keep branching for the next milestone*).

## Strong Coverage

As a result, the compiler's codebase currently has over **120 test-`Equals` programs**, that run with every merge.

# Lesson Learned

## Tianci

Coordinating a team is hard and communication between team members is important. Appreciate and learn from the diverse background of teammates. OCaml is a great language for writing compiler.

## Jimmy

Importance of having a seamless workflow and communication when collaborating for large scale development.

Also don't be afraid to tackle bigger problems.

## Jon

Make no assumptions about what people do/don't agree on. People don't like to speak up and say so when something is confusing (which, in turn, causes slowdown). That is, get everyone on the same page - even on the basics, like version control.

## Nam

Some important lessons I learned from the projects:

- Meeting is very important for everyone to get on the same page and learn from others. It was hard for everyone on our team to meet, but I think that meeting will help a lot even when not everyone can come to the meeting.
- Thinking about the architecture of the compiler and fix all the edge cases as soon as possible (edge cases take a lot of time).
- Designing the language with one good application of the language in mind.

## Lanting

Learned a lot from great teammates, it is great for people to work on the things they are good at.

# Conclusions

As stated at the beginning, EqualEqual aims to provide students an easy tool to solve lengthy and error-prone mathematical equations. With all the features we mentioned above, we believe that EqualEqual has succeeded in becoming such a user-friendly and smart language. Due to the time manner, we are not able to have it been extremely powerful. However, We expect it to be more powerful, e.g: solve complex variable circular dependency functions, in the future by using more sophisticated algorithms.

    update roles to reflect bulk of commits

Overall, we all had our hands in everything. In the large, however, here's my thought process for this commit:
- I wrote all of relation.ml, which is the crux of our language's claim to semantic analysis
- Tianci did a lot to touch base and follow up on open github issues and things that weren't getting done, so I t
- I setup the skeleton of every file and the tests, so I gave myself "Architect"
- Nam did the majority of the codegen work for our equation dependencies (again: the crux of our language's desig

commit 231ef13bf69e9c860244b1f89302564401965b20

Author: Jonathan Zacsh [jzacsh@gmail.com](mailto:jzacsh@gmail.com)

Date: Thu May 5 18:55:36 2016 -0400

```
noop(refactor) outline where bug fix should live
```

```
High-level: currently `relationCtxFolder` does its own dumb walk of contexts'  
equations, but the highly developed version in `findStmtRelator` is what we
```

```
want.
```

```
Nitty details:  
1. shares `findStmtRelator` code as a new internal API  
2. existing `find` decl analysis (`findStmtRelator`) to new, thin wrapper  
3. creates 2nd, thin wrapper for no.2, intended for `context` decl walks
```

```
GH-#86; skipping correctly analyzed eqs w/deps
```

```
These tests pass correctly through our semantic analysis, but fail to generate  
proper C. GH-#86 is all about updating our codegen pass to correctly make use of  
the new sast as of GH-#56.
```

```
Below is the listing of SAST output of these 3 tests being skipped fo codegen purposes:
```

```
...  
$ ./eqeq.native -s < tests/test-find-decl-assignment.skip.eq | sed -e '/^\\s*$/d'  
Foo : {

commit a905e6791262a7c47a97434132f639c0f3c8edef

Author: Jonathan Zacsh [jzacsh@gmail.com](mailto:jzacsh@gmail.com)

Date: Tue Apr 26 20:22:20 2016 -0400

```
bug fix: *actually* rewrite equations in SAST

uses refactor in fed505b to determine where said rewritten equation should move
to. eg, note how `b` is promoted to "independent" equation in expression 7,
caused by `b`'s redeclaration as of c43a0d2782:
```
$ make >/dev/null && ./eqeq.native -s < ./tests/test-lazyresolved-vars.eq
SomeCtx : {
    deps:
        a: [b]
        b: [c]

    indeps:
        c : ``
        5.;

    ```

    f : ``
        1. / 3.;

    ```

finds:
    "find_SomeCtx_0": {
        [0]: {
            deps:
                a: [b]
                b: [c]

            indeps:
                c : ``
                5.;

            ```

            f : ``
                1. / 3.;

            ```

        }
        [7]: {
            deps:
                a: [b]

            indeps:
                b : ``
                2.;

            ```

            c : ``
                5.;

            ```

            f : ``
                1. / 3.;

            ```

        }
    }
}

```

```

commit 69ccb84162f6d2ff8d7672a841ed9dab820c6417

Author: Jonathan Zacsh [jzacsh@gmail.com](mailto:jzacsh@gmail.com)

Date: Mon Apr 25 21:04:12 2016 -0400

noop: move fold\_left funnctions to `relation.ml`

Hopefully addresses complaint that code is too large. Is definitely clearer how the new part of the sast is being onstructed, now.

implements re-assignment of IDs and adds new test

- new test ensures we're not doing anything stupid - ie: we should be doing a tree walk down the assignments, looking.

- new compiler - as of this comment - behavior unchecked; just committing for posterity. currently produces broken C (may or may not be part of this pull request).

commit b4452cf9c9fd717621a9124dee77318ca00d9d2b  
Author: Jonathan Zacsh [jzacsh@gmail.com](mailto:jzacsh@gmail.com)  
Date: Mon Apr 11 23:19:50 2016 -0400

```
implement shell of find-expr algo[1] for equations  
1. implements all of the shell logic for Expression walk along `find` blocks,  
and leaves gaping hole in *actual* if/else `Match EXPR` with: `~-pseudocode[1]  
2. adds string functions to show what this commit does:
```

```
```sh  
make && ./eqlq.native -s < ./tests/test-lazyresolved-vars.eq  
SomeCtx : {  
  a : [b]  
  b : [c]  
  
  c : ``  
  5.;
```

```
```
"find_SomeCtx_0":
  a : [b]
  b : [c]
  c : ``
  5.;

}

```
(Note how `find_SomeCtx_0` doesn't add, just copies for now; "gaping hole" in step 1)

3. adds a bit more explicit type information to existing sast printers

[1]: https://github.com/rxie25/PLT2016Spring/blob/34bd0f5975a3e6a0/notes/whiteboard-eq-analysis.md#algorithm-in-pseuc

commit e189e4b4fe4e2538d3de4179db46f1593e0e9bb3  
Author: Jonathan Zacsh [jzacsh@gmail.com](mailto:jzacsh@gmail.com)  
Date: Mon Apr 4 01:13:42 2016 -0400

```
testing: clarify LINT about newly-passing tests

For newly passing tests, `make lint` now outputs something like:
```
LINT FOUND:      Some PASSING tests are unnecessarily skipped:
test-helloworld
test-mod
```
_(if, say, `test-helloworld` and `test-mod` are marked skip, but actually pass)_
```

default to -lm on tail-end of C-compiler args

-lm (Link "math" lib, I believe). see <http://stackoverflow.com/a/11336610/287374>  
Should be a good default since we most always will have something from `math.h`  
in our compiler's output.

GH-#15: fix bug in c058c6fdf0 checking wrong field

Need to check a find declaration's *context* exist, not its target
(target-checking comes in the well-beyond minviable version of semantic
analysis).

Was beautifully caught by two tests:
```
Running 7 tests:
    tests/test-print-basic.eq, tests/test-globalctx.skip.eq, tests/test-find-noargs.skip.eq, tests/test-arithmeti

[1] "test-print-basic" asserting target's behavior      Fatal error: exception Failure("unrecognized context, \"popula
    Result: FAIL
[2] WARNING     'test-globalctx' not implemented      Result: SKIP
[3] WARNING     'test-find-noargs' not implemented      Result: SKIP
[4] WARNING     'test-arithmetic-basic' not implemented Result: SKIP
[5] WARNING     'test-simple-equation' not implemented  Result: SKIP
[6] "test-helloworld" asserting target's behavior      Fatal error: exception Failure("unrecognized context, "a")
    Result: FAIL
[7] WARNING     'test-print-multi-find' not implemented Result: SKIP

Summary of 7 tests:      2 FAILED       5 SKIPPED       0 PASSED
```

```
BROKEN(semant) rm microc & "type" from our grammar
- cleans up old microc logic i left behind in semantic analysis
- clarifies steps i'm trying to take in this phase
- removes "bool" and "double" type that somehow slipped back into our grammar...
- uncomments, leaving code in broken state (for transparency?);
  - Specifically: among other ocaml compilation errors that I've yet to grok:
```
File "semant.ml", line 49, characters 11-49:
Error: This expression has type
    Ast.ctx_decl StringMap.t = Ast.ctx_decl Map.Make(String).t
but an expression was expected of type
    'a -> Ast.ctx_decl StringMap.t * Ast.ctx_decl
Command exited with code 2.
Compilation unsuccessful after building 13 targets (0 cached) in 00:00:00.
```

GH-#14: demonstrate "skip" tests for TDD coding

Takes a first example of broken codegen (we knowingly left out of GH-#12 to get min-viable) and uses it to show how to easily write SKIP tests ahead of time, so we can write as many example programs as we can encode our expectations in the codebase and see them printed w/every `make test` :D

```
src/e2e-tests.sh | 7 ++++++

```
fix e2e bash hack (never again): passing now!

1. .gitignore latest version of log file this test outputs
2. Makefile doesn't need to point to tests/ dir, so stop doing that
3. do better job of handling test files as args (ugh.. bash)
4. bells/whistles:
   - adds test summary beginning/end
   - correctly captures test status and prints relevant message
   - breaks less easily with strange/accidental args
```

updates docs & test script enabling auto-completion

test script was named identically to directory, so i couldn't autocomplete it easily in my shell :) i can now. also updated documentation

commit cee46f004d42fb4014c22dc2e1eef06bc7ef45b8

Author: Jonathan Zacsh [jzacsh@gmail.com](mailto:jzacsh@gmail.com)  
Date: Wed Mar 23 18:20:40 2016 -0400

total rewrite of ./testcall.sh script

```
cd, you can now run  
```bash  
$ make test  
$ make TEST_OPTS=-dv test  # equiv to passing args to script: ./testall.sh -dv  
```
```

unfortunately, rewrote e2e test script from ground up since:

- a) found it too hard to pick apart LLVM/concepts and add our own (ie: we don't target machine executable)
- b) i can read this bash now
- c) not invented here syndrome
- d) not invented here syndrome

src/Makefile | 9 +-

```

```
GH-#8: outlines TODOs and resturctures for EqEq
```

```
Note: `check_{stmt,expr}` have moved to top-level of `check` API, as they need  
to be performed for both `find` and Context blocks. Further put large TODO in  
place where we expect all our interesting context-checking to happen....
```

```
Namely: that unknown variables go into a local `equations_to_solve` so we can  
complain later when we call `check_find` and see a find expression that tries to  
solve something without the necessary missing pieces

```
GH-#8 update `check` API of semantic analysis
```

```
**NOTE**: this doesn't *fix* our semantic analysis, just takes the first  
shareable step: renames the top-level API signature to clarify what the semantic  
analysis *should* be iterating over (ie: what our `ast`/LRM thinks an EqEq  
program *is*).
```

```
**Next step**: walk through each `contexts` and `finds` reference in this file  
and update it to match our real AST, and actually perform checks that we really  
want to perform (eg: "is this `find` applying to an actual context we know  
about?").

fixe issue #2 "context"s begin with uppercase  
  
- shift/reduce conflict fixed. parser-generator found that our:  
  1. contexts and equations look nearly identical. We acknowledge this throughout our LRM by capitalizing our context's names, eg: `Euclid`, not `euclid` (though were' not perfectly consistent... though that's true of our LRM genearly). I cannot find that we specified this formally anywhere, but I recall us talking about it.  
  2. our context definition matched the rest of our program, practically. I believe we never caught this writing the LRM, but I'm making the call for us that it is okay to limit contexts to *only* only equations (and multi-line) equations. that is: no `print` statements in contexts. not sure what other negative impact this has (if that's even a negative impact).  
- tangentially: fills in `string_of_[grammar]` functions that were quietly broken by previous major refactor, ddc7fa475f09d4d4dac7e9d1a64f1a8ed6f2956f
```

```
Example output of `menhir --explain parser.mly`, before this commit:  
```
```

```
** Conflict (shift/reduce) in state 73.  
** Token involved: ID  
** This state is reached from program after reading:
```

```
decls CTX ASSIGN LBRACE
```

```

** The derivations that appear below have the following common factor:
** (The question mark symbol (?) represents the spot where the derivations begin to differ.)

program
decls EOF
decls ctxtdecl
    CTX ASSIGN LBRACE ctx RBRACE
        (?)

** In state 73, looking ahead at ID, shifting is permitted
** because of the following sub-derivation:

funcdecl
. ID ASSIGN LBRACE stmt_list RBRACE

** In state 73, looking ahead at ID, reducing production
** stmt_list ->
** is permitted because of the following sub-derivation:

stmt_list
stmt_list stmt // lookahead token appears because stmt can begin with ID
```

```

rm microc-specific scanner/parser logic

.. leaves w/1 shift/reduce in place to be tackled next

Doesn't get scanner & parser 100% to eeq's LRM, but 99.9% there. This commit
focuses simply on removing scanner/parser logic that do *not* exist in eeq, and
leaves "TODO"-comments where more needs to be done (eg: see `parser.mly`'s TODO
on global-level multi-line equations).

This commit also documents current state of this branch (and this commit) fully
in ./notes/microc-to-eqeq.md, which has been copy/pasted here as my change
summary:
> # Changes to MicroC Codebase
>
> At a high-level, this refactor:
> - Rebrands to "microc" where convenient (eg: in comments, just in files touched)
> - updates scanner and parser to adhere to our LRM (everything described below)
>
> Below was written while trying to keep track of removals that are taking place,
> in refactoring MicroC to match our LRM. This is necessary as a single list
> rather than `git diff` which includes implementation-details' tangential
> details. In other words, this document:
> - includes, "change peg to be round"
> - leaves out, "change holes 1,2,3,4,5,6,... to take round peg"

commit 5513f25758240b6214bfc5c4fc71212396fd1768

Author: Jonathan Zacsh [jzacsh@gmail.com](mailto:jzacsh@gmail.com)

Date: Sat Mar 12 09:53:52 2016 -0500

```
kick off e2e testing efforts with a full snippet
```

```
note: too complicated to be useful for "hello world" we want to target.
```

```
adds an ` .eq` (for EqualsEquals) test program forked from test-gcd.mc. Can be
run with:
```

```
```bash
./testall.sh tests/*.eq
```
```

```

completed all major TODOs on LRM exceptions, below
```

```
exceptions, not completed:
```

- "ensure we have page numbers" - not sure how to do this, and doesn't seem important enough to block on
- "ensure code snippet is colored" - too much of a pain to do, and edwards' own code snippets are never highlighted. instead just gave a background color as

he does in his own lecture slides  
- "review TODOs with TA/edwards" - in process of setting up a meeting with TA now; unfortunately couldn't meet with TA over the weekend, so our LRM's many open questions don't have much input  
- "as group [...] scanners.mll" already listed as an AI elsewhere (eg: github issue)

lots of last minute inconsistency fixes to our LRM

- "ASCII" reference made slightly incorrect by our decision on string-literals  
- in a PDF our long comments in code go off the page, need to wrap them manually  
- snippets at bottom of doc weren't reviewed for consistency with new LRM  
- GCD example was old  
- function and function-param-list was referenced  
- semi-colons missing everywhere

commit 51931e59c744777f9822c98b00f4feca10fed02d  
Author: Jonathan Zacsh jzacsh@gmail.com  
Date: Sat Mar 5 23:06:26 2016 -0500
```

```
reworded/revisd first major section, "Design Implementation"  
- was all over the place with:  
- lots of repitition  
- out of order  
- added a ton of `TODO`'s for us to address as a group
```

Date: Sat Mar 5 18:45:39 2016 -0500

rephrase for simpler titles of intro

- mark "target"-section's port as complete
- splits existing "what is a program" in 1/2 to show a "hello world"
