CS3157: Advanced Programming

Lecture #9
Oct 31

Shlomo Hershkop
shlomo@cs.columbia.edu

Outline

- Feedback
- Arrays
- Pointers
- functions
- function arguments
- arrays and pointers as function arguments

- Reading
  - Chapter 5,6-6.3

Arrays again

- Arrays and pointers are strongly related in C

```
int a[10];
int *pa;
pa = &a[0];
pa = a;
```

- pointer arithmetic is meaningful with arrays:
- if we do

```
Pntr = &a[0]
```

- then

```
*(Pntr +1) =
```

- points to a[1]

- Remember difference between *(Pntr) + 1 and (*Pntr +1)
- Note that an array name is a pointer, so we can also do *(a+1) and in general: *(a + i) == a[i] and so are a + i == &a[i]
- The difference:
  - an array name is a constant, and a pointer is not
  - so we can do: Pntr = a and Pntr ++
- But we can NOT do: a = Pntr or a++ pr or Pntr = &a

Note

- When an array name is passed to a function, what is passed is the beginning of the array

5

Remember

- a pointer contains the address of an object (but not in the OOP sense)
- allows one to access object “indirectly”
- & = unary operator that gives address of its argument
- * = unary operator that fetches contents of its argument (i.e., its argument is an address)
- note that & and * bind more tightly than arithmetic operators
- you can print the value of a pointer with the formatting character %p

6

code

```
#include <stdio.h>
main() {
  int x, y;     // declare two ints
  int *px;      // declare a pointer to an int
  x = 3;        // initialize x
  px = &x;
  y = *px;
 printf( "x=%d px=%p y=%d\n",x,px,y );
}
```

7

Dynamic Memory Allocation

- used when you don’t know at compile-time how much memory to allocate
- pre-allocated memory comes from the “stack”
- dynamically allocated memory comes from the “heap”
- family of functions in stdlib, including:

```
void *malloc( size_t size );
void *realloc( void *ptr, size_t size );
void free( void * );
```

- malloc and realloc return a generic pointer (void *) and you have to “cast” the return to the type of pointer you want

8

Malloc.c

```
#include <stdio.h>
#include <stdlib.h>
#define BLKSIZ 10
main() {
  FILE *fp;
  char *buf, k;
  int  bufsiz, i;
  // open file for reading
  if (( fp = fopen( "myfile.dat","r" )) == NULL ) {
    perror( "error opening myfile.dat" );
    exit( 1 );
  }
  // allocate memory for input buffer
  bufsiz = BLKSIZ;
  buf = (char *)malloc( sizeof(char)*bufsiz );
```

II

```
// read contents of file
  i = 0;
  while (( k = fgetc( fp )) != EOF ) {
    buf[i++] = k;
    if ( i == bufsiz ) {
      bufsiz += BLKSIZ;
      buf = (char *)realloc( buf,sizeof(char)*bufsiz );
    }
  }
  if ( i >= bufsiz-1 ) {
    bufsiz += BLKSIZ;
    buf = (char *)realloc( buf,sizeof(char)*bufsiz );
  }
  buf[i] = '\0';
  // output file contents to the screen
  printf( "buf=[%s]\n",buf );
  // close file
  fclose( fp );
} // end main()
```

Dynamic memory

- malloc() allocates a block of memory:

```
void *malloc( size_t size );
```

- lifetime of the block is until memory is freed, with free():

```
void free( void *ptr );
```

- example:

```
int *dynvec, num_elements;
printf( "how many elements do you want to enter? " );
scanf( "%d", &num_elements );
dynvec = (int *)malloc( sizeof(int) * num_elements );
```

Memory leaking

- memory leaks— memory allocated that is never freed:

```
char *combine( char *s, char *t ) {
u = (char *)malloc( strlen(s) + strlen(t) + 1 );
if ( s != t ) {
strcpy( u, s );
strcat( u, t );
return u;
}
else {
return 0;
}
} /* end of combine() */
```

- u should be freed if return 0; is executed
- but you don't need to free it if you are still using it!

Example 2

```
int main(void) {

  char *string1 = (char*)malloc(sizeof(char)*50);
  char *string2 = (char*)malloc(sizeof(char)*50);
  scanf("%s",string2);
  string1 = strong2;

  ...
  free(string2);
  free(string1); ///????

  return 0
  }
```

13

Memory leak tools

- Purify
- Valgrind
- Insure++
- Memwatch
- Memtrace
- Dmalloc

14

Dynamic memory

- note: malloc() does not initialize data
- you can allocate and initialize with "calloc":

void *calloc(size_t nmemb, size_t size);

  - calloc allocates memory for an array of nmemb elements of size bytes each and returns a pointer to the allocated memory. The memory is set to zero.

- you can also change size of allocated memory blocks with "realloc":

void *realloc(void *ptr, size_t size);

  - realloc changes the size of the memory block pointed to by ptr to size bytes. The contents will be unchanged to the minimum of the old and new sizes; newly allocated memory will be uninitialized.

- these are all functions in stdlib.h
- for more information: unix$ man malloc

15

Dynamic arrays

- "arrays" are defined by specifying an element type and number of elements
  - statically:

```
int vec[100];
char str[30];
float m[10][10];
```

  - dynamically:

```
int *dynvec, num_elements;
printf( "how many elements do you want to enter? " );
scanf( "%d", &num_elements );
dynvec = (int *)malloc( sizeof(int) * num_elements );
```

- for an array containing N elements, indeces are 0..N-1
- stored as a linear arrangement of elements
- often similar to pointers

16

Dynamic arrays II

- C does not remember how large arrays are (i.e., no length attribute, unlike Java)
- given:

```
int x[10];
x[10] = 5; /* error! */
```

- ERROR! because you have only defined x[0]..x[9] and the memory location where x[10] is can become something else...

- sizeof x gives the number of bytes in the array
- sizeof x[0] gives the number of bytes in one array element
- You can compute the length of x via:

```
int length_x = sizeof x / sizeof x[0];
```

17

Arrays cont.

- when an array is passed as a parameter to a function:
  - The size information is not available inside the function
  - array size is typically passed as an additional parameter

```
printArray( x, length_x );
```

  - or globally

```
#define VECSIZE 10
int x[VECSIZE];
```

18

arrays

- array elements are accessed using the same syntax as in Java: array[index]
- C does not check whether array index values are sensible (i.e., no bounds checking)
- e.g., x[-1] or vec[10000] will not generate a compiler warning!
- if you're lucky, the program crashes with Segmentation fault (core dumped)

19

Dynamically allocated arrays

- C references arrays by the address of their first element
- array is equivalent to &array[0]
- you can iterate through arrays using pointers as well as indexes:

```
int *v, *last;
int sum = 0;
last = &x[length_x-1];
for ( v = x; v <= last; v++ )
sum += *v;
```

20

Code

```
#include <stdio.h>
#define MAX 12
int main( void ) {
int x[MAX]; /* declare 12-element array */
int i, sum;
for ( i=0; i<MAX; i++ ) { x[i] = i; }
/* here, what is value of i? of x[i]? */
sum = 0;
for ( i=0; i<MAX; i++ ) { sum += x[i]; }
printf( "sum = %d\n",sum );
} /* end of main() */
```

21

Code 2

```
#include <stdio.h>
#define MAX 10
int main( void ) {
int x[MAX]; /* declare 10-element array */
int i, sum, *p;
p = &x[0];
for ( i=0; i<MAX; i++ ) { *p = i + 1; p++; }
p = &x[0];
sum = 0;
for ( i=0; i<MAX; i++ ) { sum += *p; p++; }
printf( "sum = %d\n",sum );
} /* end of main() */
```

22

2 dimensional arrays

- 2-dimensional arrays
- int weekends[52][2];
- you can use indices or pointer math to locate elements in the array
  - weekends[0][1]
  - weekends+1
- `weekends[2][1]` is same as `*(weekends+2*2+1)`, but NOT the same as `*weekends+2*2+1` (which is an integer)!

23

Functions defintions

- similar to methods in java but there aren't classes in C and functions can't be overloaded
- syntax:

```
<type> name( argument-list-if-any )
argument-declarations-if-any;
{
function-body;
return [<expression>];
}
or
<type> name( argument-list-if-any-including-declarations )
  {
function-body;
return [<expression>];
}
```

24

Functions II

- A program is just a set of individual function definitions
- char promotes to int in any expression, so you don't need to define functions that return char (only int)
- int is the default return type
- function arguments are "passed by value"
- the function receives a temporary copy of the value of the argument (not the argument's address)
- functions with a variable number of arguments use the first argument to tell it how many arguments will follow (e.g., printf)
- function arguments
  - since function arguments are "passed by value", you can use pointers to have a function change the value of a variable

25

swap

```
void swapNot( int a,int b ) {
  int tmp = a;
  a = b;
  b = tmp;
} // end swapNot()

void swap( int *a,int *b ) {
  int tmp = *a;
  *a = *b;
  *b = tmp;
} // end swap()
```

26

swap

```
int x, y;        // declare two ints
int *px, *py;    // declare two pointers to ints
x = 3;  // initialize x
y = 5;  // initialize y

printf( "before: x=%d y=%d\n",x,y );

swapNot( x,y );
printf( "after swapNot: x=%d y=%d\n",x,y );

px = &x; // set px to point to x (i.e., x's address)
py = &y; // set py to point to y (i.e., y's address)

printf( "the pointers: px=%p py=%p\n",px,py );

swap( px,py );
printf( "after swap with pointers: x=%d y=%d px=%p py=%p\n",x,y,px,py );

// you can also do this directly, without px and py:
swap( &x,&y );
printf( "after swap without pointers: x=%d y=%d\n",x,y );
```

27

Creating your own types

- Equivalent to a class idea in other programming languages

```
struct name {

  types
  }
```

28

example

```
struct point {
   int x;
   int y;
  }
```

- Can also create anonymous structs
- Usage:

```
struct point a,b;
a.x = 5;
a.y = 10;
```

29

Nesting

```
struct rect {
    struct point pt1;
    struct point p2;
  }
```

- Use:
  struct rect largeScreen;

30

Making space

- Remember in the proceeding examples, simple types so memory is automatically allocated (in a sense).
- struct student {
      char * name;
      int age;
  }

  struct student a;
  a.name = (char*)malloc(sizeof(char)*25));
  …

31

Use in functions

```
struct point makePoint(int x, int y)
  {
      struct point temp;
      temp.x = x;
      temp.y = y;
      return temp;
  }
```

32

Operations

- Copy
- Assignments
- & (addressing)
- Accessing members

- Can not compare 2 structs

33

Structs and pointers

- struct point *example;

  (*example).x

  what does
  *example.x mean?

  Shortcut:
  example->x

34

Passing functions

- Say you have:
  int power(int a, int b)
- Can pass into function the following way:
- char* calculate(int (* mathy)(int,int), int x, char b);
  defines a function which returns a char pointer and takes a function pointer called mathy, which returns an int and takes 2 ints as arguments, along with and int and a char.
- Then can say:
  calculate((int(*)(int,int))power(x1,x2), x35351, t);

35

Next time

- Do reading
- See you in lab Wednesday.
- Next Monday, academic holiday. (2 labs in a row).

36
