### 1.0 EZ-USB SX2™ Features

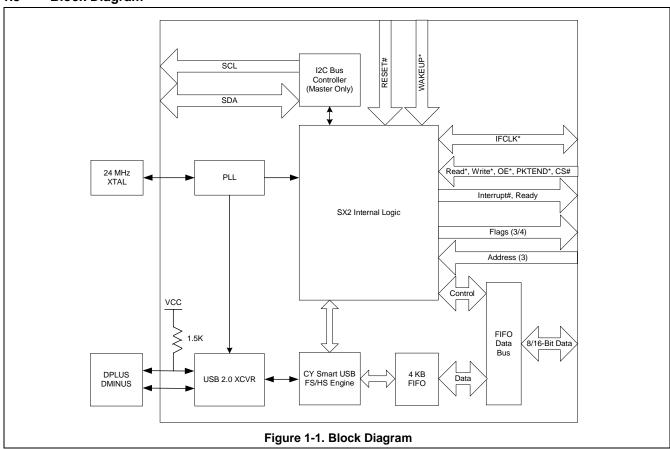

#### 1.1 Introduction

The EZ-USB SX2™ USB interface device is designed to work with any external master, such as standard microprocessors, DSPs, ASICs, and FPGAs to enable USB 2.0 support for any peripheral design. SX2 has a built-in USB transceiver and Serial Interface Engine (SIE), along with a command decoder for sending and receiving USB data. The controller has four endpoints that share a 4-KB FIFO space for maximum flexibility and throughput, as well as Control Endpoint 0. SX2 has three address pins and a selectable 8- or 16- bit data bus for command and data input or output.

### 1.2 Features

- USB 2.0-certified compliant
- Operates at high (480 Mbps) or full (12 Mbps) speed
- Supports Control Endpoint 0:
  - Used for handling USB device requests
- Supports four configurable endpoints that share a 4-KB FIFO space
  - Endpoints 2, 4, 6, 8 for application-specific control and data
- Standard 8- or 16-bit external master interface
  - Glueless interface to most standard microprocessors DSPs, ASICs, and FPGAs
  - Synchronous or Asynchronous interface
- Integrated phase-locked loop (PLL)
- 3.3V operation, 5V tolerant I/Os
- 56-pin SSOP and QFN package
- . Complies with most device class specifications

#### 1.3 Block Diagram

Document #: 38-08013 Rev. \*B

# 2.0 Applications

- DSL modems
- ATA interface
- · Memory card readers
- · Legacy conversion devices
- Cameras
- Scanners
- Home PNA
- Wireless LAN
- MP3 players
- Networking
- Printers

The "Reference Designs" section of the Cypress web site provides additional tools for typical USB applications. Each reference design comes complete with firmware source code and object code, schematics, and documentation. Please see the Cypress web site at www.cypress.com.

### 2.1 System Diagram

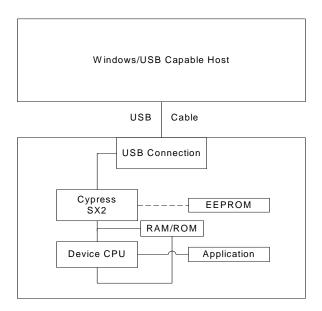

Figure 2-1. Example USB System Diagram

### 3.0 Functional Overview

#### 3.1 USB Signaling Speed

SX2 operates at two of the three rates defined in the Universal Serial Bus Specification Revision 2.0, dated April 27, 2000:

- Full-speed, with a signaling bit rate of 12 Mbits/s
- High-speed, with a signaling bit rate of 480 Mbits/s.

SX2 does not support the low-speed signaling rate of 1.5 Mbits/s.

#### 3.2 Buses

SX2 features:

- · A selectable 8- or 16-bit bidirectional data bus
- An address bus for selecting the FIFO or Command Interface.

#### 3.3 Boot Methods

During the power-up sequence, internal logic of the *SX2* checks for the presence of an I<sup>2</sup>C-compatible EEPROM.<sup>[1,2]</sup> If it finds an EEPROM, it will boot off the EEPROM. When the presence of an EEPROM is detected, the *SX2* checks the value of first byte. If the first byte is found to be a 0xC4, the *SX2* loads the next two bytes into the IFCONFIG and POLAR registers, respectively. If the fourth byte is also 0xC4, the *SX2* enumerates using the descriptor in the EEPROM, then signals to the external master when enumeration is complete via an ENUMOK interrupt (Section 3.4). If no EEPROM is detected, the *SX2* relies on the external master for the descriptors. Once this descriptor information is receive from the external master, the *SX2* will connect to the USB bus and enumerate.

#### 3.3.1 EEPROM Organization

The valid sequence of bytes in the EEPROM are displayed below.

Table 3-1. Descriptor Length Set to 0x06: Default Enumeration

Byte Index	Description
0	0xC4
1	IFCONFIG
2	POLAR
3	0xC4
4	Descriptor Length (LSB):0x06
5	Descriptor Length (MSB): 0x00
6	VID (LSB)
7	VID (MSB)
8	PID (LSB)
9	PID (MSB)
10	DID (LSB)
11	DID (MSB)

Table 3-2. Descriptor Length Not Set to 0x06

I abic o L.	Decemptor Longin Not out to exce
Byte Index	Description
0	0xC4
1	IFCONFIG
2	POLAR
3	0xC4
4	Descriptor Length (LSB)
5	Descriptor Length (MSB
6	Descriptor[0]
7	Descriptor[1]
8	Descriptor[2]

- 0xC4: This initial byte tells the SX2 that this is a valid EEPROM with configuration information.
- **IFCONFIG**: This byte contains the settings for the IFCONFIG register. The IFCONFIG register bits are defined in Section 7.1. If the external master requires an interface configuration different from the default, that interface can be specified in this byte.
- **POLAR**: This byte contains the polarities of the interface signals. The POLAR register bits are defined in Section 7.3. If the external master requires signal polarities different from the default, those polarities can be specified in this byte.
- **Descriptor**: This next byte determines whether or not the *SX2* loads the descriptor from the EEPROM. If this byte = 0xC4, the *SX2* will load the descriptor starting with the next byte. If this byte does not equal 0xC4, the *SX2* will wait for descriptor information from the external master.

#### Notes

- Because there is no direct way to detect which EEPROM type (single or double address) is connected, SX2 uses the EEPROM address pins A2, A1, and A0
  to determine whether to send out one or two bytes of address. Single-byte address EEPROMs (24LC01, etc.) should be strapped to address 000 and doublebyte EEPROMs (24LC64, etc.) should be strapped to address 001.
- The SCL and SDA pins must be pulled up for this detection method to work properly, even if an EEPROM is not connected. Typical pull-up values are 2.2K 10K Ohms.

Document #: 38-08013 Rev. \*B

- Descriptor Length: The next two bytes indicate the length of the descriptor contained in the EEPROM. The length is loaded least significant byte (LSB) first, then most significant byte (MSB).
- Byte 7 Starts Descriptor Information: The descriptor can be a maximum of 500 bytes.

#### 3.3.2 Default Enumeration

An optional default descriptor can be used to simplify enumeration. Only the Vendor ID (VID), Product ID (PID), and Device ID (DID) need to be loaded by the *SX2* for it to enumerate with this default set-up. This information is either loaded from an EEPROM in the case when the presence of an EEPROM (*Table 3-1*) is detected, or the external master may simply load a VID, PID, and DID when no EEPROM is present. In this default enumeration, the *SX2* uses the in-built default descriptor (refer to Section 12.0).

If the descriptor length loaded from the EEPROM is 6, *SX2* will load a VID, PID, and DID from the EEPROM and enumerate. The VID, PID, and DID are loaded LSB, then MSB. For example, if the VID, PID, and DID are 0x0547, 0x1002, and 0x0001, respectively, then the bytes should be stored as:

• 0x47, 0x05, 0x02, 0x10, 0x01, 0x00.

If there is no EEPROM, *SX2* will wait for the external master to provide the descriptor information. To use the default descriptor, the external master must write to the appropriate register (0x30) with descriptor length equal to 6 followed by the VID, PID, and DID. Refer to Section 4.2 for further information on how the external master may load the values.

The default descriptor enumerates four endpoints as listed in the following page:

- Endpoint 2: Bulk out, 512 bytes in high-speed mode, 64 bytes in full-speed mode
- Endpoint 4: Bulk out, 512 bytes in high-speed mode, 64 bytes in full-speed mode
- Endpoint 6: Bulk in, 512 bytes in high-speed mode, 64 bytes in full-speed mode
- Endpoint 8: Bulk in, 512 bytes in high-speed mode, 64 bytes in full-speed mode.

The entire default descriptor is listed in Section 12.0 of this data sheet.

### 3.4 Interrupt System

#### 3.4.1 Architecture

The SX2 provides an output signal that indicates to the external master that the SX2 has an interrupt condition, or that the data from a register read request is available. The SX2 has six interrupt sources: SETUP, EP0BUF, FLAGS, ENUMOK, BUSACTIVITY, and READY. Each interrupt can be enabled or disabled by setting or clearing the corresponding bit in the INTENABLE register.

When an interrupt occurs, the INT# pin will be asserted, and the corresponding bit will be set in the Interrupt Status Byte. The external master reads the Interrupt Status Byte by strobing SLRD/SLOE. This presents the Interrupt Status Byte on the lower portion of the data bus (FD[7:0]). Reading the Interrupt Status Byte automatically clears the interrupt. Only one interrupt request will occur at a time; the SX2 buffers multiple pending interrupts.

If the external master has initiated a register read request, the *SX2* will buffer interrupts until the external master has read the data. This insures that after a read sequence has begun, the next interrupt that is received from the *SX2* will indicate that the corresponding data is available. Following is a description of this ITENABLE register.

### 3.4.2 ITENABLE Register Bit Definition

### Bit 7: SETUP

If this interrupt is enabled, and the *SX2* receives a set-up packet from the USB host, the *SX2* asserts the INT# pin and sets bit 7 in the Interrupt Status Byte. This interrupt only occurs if the set-up request is not one that the *SX2* automatically handles. For complete details on how to handle the SETUP interrupt, refer to Section 5.0 of this data sheet.

#### Bit 6: EP0BUF

If this interrupt is enabled, and the Endpoint 0 buffer becomes available to the external master for read or write operations, the *SX2* asserts the INT# pin and sets bit 6 in the Interrupt Status Byte. This interrupt is used for handling the data phase of a set-up request. For complete details on how to handle the EP0BUF interrupt, refer to Section 5.0 of this data sheet.

### Bit 5: FLAGS

If this interrupt is enabled, and any OUT endpoint FIFO's state changes from empty to not-empty, the *SX2* asserts the INT# pin and sets bit 5 in the Interrupt Status Byte. This is an alternate way to monitor the status of OUT endpoint FIFOs instead of using the FLAGA-FLAGD pins, and can be used to indicate when an OUT packet has been received from the host.

#### Bit 4: ENUMOK

If this interrupt is enabled and the SX2 receives a SET\_CONFIGURATION request from the USB host, the SX2 asserts the INT# pin and sets bit 2 in the Interrupt Status Byte. This event signals the completion of the SX2 enumeration process.

Document #: 38-08013 Rev. \*B Page 10 of 50

### **Bit 1: BUSACTIVITY**

If this interrupt is enabled, and the *SX2* detects either an absence or resumption of activity on the USB bus, the *SX2* asserts the INT# pin and sets bit 1 in the Interrupt Status Byte. This usually indicates that the USB host is either suspending or resuming or that a self-powered device has been plugged in or unplugged. If the *SX2* is bus-powered, the external master must put the *SX2* into a low-power mode after detecting a USB suspend condition to be USB-compliant.

#### Bit 0: READY

If this interrupt is enabled, bit 0 in the Interrupt Status Byte is set when the SX2 has powered up and performed a self-test. The external master should always wait for this interrupt before trying to read or write to the SX2, unless an external EEPROM with a valid descriptor is present. If an external EEPROM with a valid descriptor is present, the ENUMOK interrupt will occur instead of the READY interrupt after power up. A READY interrupt will also occur if the SX2 is awakened from a low-power mode via the WAKEUP pin. This READY interrupt indicates that the SX2 is ready for commands or data.

### 3.5 Resets and Wakeup

#### 3.5.1 Reset

An input pin (RESET#) resets the chip. The internal PLL stabilizes approximately 7.6 ms after  $V_{CC}$  has reached 3.3V. Typically, an external RC network (R = 100 K Ohms, C = 0.1 uf) is used to provide the RESET# signal.

#### 3.5.2 USB Reset

When the SX2 detects a USB Reset condition on the USB bus, SX2 handles it like any other enumeration sequence. This means that SX2 will enumerate again and assert the ENUMOK interrupt to let the external master know that it has enumerated. The external master will then be responsible for configuring the SX2 for the application. The external master should also check whether SX2 enumerated at High or Full speed in order to adjust the EPxPKTLENH/L register values accordingly. The last initialization task is for the external master to flush all of the SX2 FIFOs.

#### 3.5.3 Wakeup

The SX2 exits its low-power state when one of the following events occur:

- USB bus signals a resume. The SX2 will assert a BUSACTIVITY interrupt.
- The external master asserts the WAKEUP pin. The SX2 will assert a READY interrupt.

#### 3.6 Endpoint RAM

#### 3.6.1 Size

- Control endpoint: 64 Bytes: 1 x 64 bytes (Endpoint 0).
- FIFO Endpoints: 4096 Bytes: 8 x 512 bytes (Endpoint 2, 4, 6, 8).

### 3.6.2 Organization

- EP0-Bidirectional Endpoint 0, 64-byte buffer.
- EP2, 4, 6, 8–Eight 512-byte buffers, bulk, interrupt, or isochronous. EP2 and EP6 can be either double-, triple-, or quad-buffered. EP4 and EP8 can only be double-buffered. For high-speed endpoint configuration options, see *Figure 3-1*.

#### 3.6.3 Endpoint Configurations (High-speed Mode)

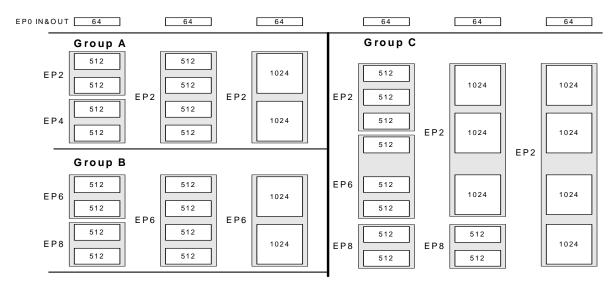

Figure 3-1. Endpoint Configuration

Endpoint 0 is the same for every configuration as it serves as the CONTROL endpoint. For Endpoints 2, 4, 6, and 8, refer to Figure 3-1. Endpoints 2, 4, 6, and 8 may be configured by choosing either:

- One configuration from Group A and one from Group B
- One configuration from Group C.

Some example endpoint configurations are as follows.

- EP2: 1024 bytes double-buffered, EP6: 512 bytes quad-buffered.
- EP2: 512 bytes double-buffered, EP4: 512 bytes double-buffered, EP6: 512 bytes double-buffered, EP8: 512 bytes double buffered.
- EP2: 1024 bytes quad-buffered.

#### 3.6.4 Default Endpoint Memory Configuration

At power-on-reset, the endpoint memories are configured as follows:

- EP2: Bulk OUT, 512 bytes/packet, 2x buffered.
- EP4: Bulk OUT, 512 bytes/packet, 2x buffered.
- EP6: Bulk IN, 512 bytes/packet, 2x buffered.
- EP8: Bulk IN, 512 bytes/packet, 2x buffered.

#### 3.7 External Interface

The SX2 presents two interfaces to the external master.

- 1. A FIFO interface through which EP2, 4, 6, and 8 data flows.
- 2. A command interface, which is used to set up the SX2, read status, load descriptors, and access Endpoint 0.

#### 3.7.1 Architecture

The SX2 slave FIFO architecture has eight 512-byte blocks in the endpoint RAM that directly serve as FIFO memories and are controlled by FIFO control signals (IFCLK, CS#, SLRD, SLWR, SLOE, PKTEND, and FIFOADR[2:0]).

The SX2 command interface is used to set up the SX2, read status, load descriptors, and access Endpoint 0. The command interface has its own READY signal for gating writes, and an INT# signal to indicate that the SX2 has data to be read, or that an interrupt event has occurred. The command interface uses the same control signals (IFCLK, CS#, SLRD, SLWR, SLOE, and FIFOADR[2:0]) as the FIFO interface, except for PKTEND.

#### 3.7.2 Control Signals

#### 3.7.2.1 FIFOADDR Lines

The SX2 has three address pins that are used to select either the FIFOs or the command interface. The addresses correspond to the following table.

Table 3-3. FIFO Address Lines Setting

Address/Selection	FIFOADR2	FIFOADR1	FIFOADR0
FIFO2	0	0	0
FIFO4	0	0	1
FIFO6	0	1	0
FIFO8	0	1	1
COMMAND	1	0	0
RESERVED	1	0	1
RESERVED	1	1	0
RESERVED	1	1	1

The *SX2* accepts either an internally derived clock (30 or 48 MHz) or externally supplied clock (IFCLK, 5-50 MHz), and SLRD, SLWR, SLOE, PKTEND, CS#, FIFOADR[2:0] signals from an external master. The interface can be selected for 8- or 16- bit operation by an internal configuration bit, and an Output Enable signal SLOE enables the data bus driver of the selected width. The external master must ensure that the output enable signal is inactive when writing data to the *SX2*. The interface can operate either asynchronously where the SLRD and SLWR signals act directly as strobes, or synchronously where the SLRD and SLWR act as clock qualifiers. The optional CS# signal will tristate the data bus and ignore SLRD, SLWR, PKTEND.

The external master reads from OUT endpoints and writes to IN endpoints, and reads from or writes to the command interface.

#### 3.7.2.2 Read: SLOE and SLRD

In synchronous mode, the FIFO pointer is incremented on each rising edge of IFCLK while SLRD is asserted. In asynchronous mode, the FIFO pointer is incremented on each asserted-to-deasserted transition of SLRD.

SLOE is a data bus driver enable. When SLOE is asserted, the data bus is driven by the SX2.

#### 3.7.2.3 Write: SLWR

In synchronous mode, data on the FD bus is written to the FIFO (and the FIFO pointer is incremented) on each rising edge of IFCLK while SLWR is asserted. In asynchronous mode, data on the FD bus is written to the FIFO (and the FIFO pointer is incremented) on each asserted-to-deasserted transition of SLWR.

#### 3.7.2.4 PKTEND

PKTEND commits the current buffer to USB. To send a short IN packet (one which has not been filled to max packet size determined by the value of PL[X:0] in EPxPKTLENH/L), the external master strobes the PKTEND pin.

#### 3.7.3 IFCLK

The IFCLK pin can be configured to be either an input (default) or an output interface clock. Bits IFCONFIG[7:4] define the behavior of the interface clock. To use the SX2's internally-derived 30- or 48-MHz clock, set IFCONFIG.7 to 1 and set IFCONFIG.6 to 0 (30 MHz) or to 1 (48 MHz). To use an externally supplied clock, set IFCONFIG.7=0 and drive the IFCLK pin (5 MHz – 50 MHz). The input or output IFCLK signal can be inverted by setting IFCONFIG.4=1.

#### 3.7.4 FIFO Access

An external master can access the slave FIFOs either asynchronously or synchronously:

- Asynchronous-SLRD, SLWR, and PKTEND pins are strobes.
- Synchronous–SLRD, SLWR, and PKTEND pins are enables for the IFCLK clock pin.

An external master accesses the FIFOs through the data bus, FD [15:0]. This bus can be either 8- or 16-bits wide; the width is selected via the WORDWIDE bit in the EPxPKTLENH/L registers. The data bus is bidirectional, with its output drivers controlled by the SLOE pin. The FIFOADR[2:0] pins select which of the four FIFOs is connected to the FD [15:0] bus, or if the command interface is selected.

#### 3.7.5 FIFO Flag Pins Configuration

The FIFO flags are FLAGA, FLAGB, FLAGC, and FLAGD. These FLAGx pins report the status of the FIFO selected by the FIFOADR[2:0] pins. At reset, these pins are configured to report the status of the following:

- FLAGA reports the status of the programmable flag.
- FLAGB reports the status of the full flag.
- · FLAGC reports the status of the empty flag.
- FLAGD defaults to the CS# function.

The FIFO flags can either be indexed or fixed. Fixed flags report the status of a particular FIFO regardless of the value on the FIFOADR [2:0] pins. Indexed flags report the status of the FIFO selected by the FIFOADR [2:0]pins.<sup>[3]</sup>

### 3.7.6 Default FIFO Programmable Flag Set-up

By default, FLAGA is the Programmable Flag (PF) for the endpoint being pointed to by the FIFOADR[2:0] pins. For EP2 and EP4, the default endpoint configuration is BULK, OUT, 512, 2x, and the PF pin asserts when the entire FIFO has greater than/equal to 512 bytes. For EP6 and EP8, the default endpoint configuration is BULK, IN, 512, 2x, and the PF pin asserts when the entire FIFO has less than/equal to 512 bytes. In other words, EP6/8 report a half-empty state, and EP2/4 report a half-full state. The polarity of the programmable flag is set to active low and cannot be altered.

### 3.7.7 FIFO Programmable Flag (PF) Set-up

Each FIFO's programmable-level flag (PF) asserts when the FIFO reaches a user-defined fullness threshold. That threshold is configured as follows:

- 1. For OUT packets: The threshold is stored in PFC12:0. The PF is asserted when the number of bytes *in the entire FIFO* is less than/equal to (DECIS = 0) or greater than/equal to (DECIS = 1) the threshold.
- 2. For IN packets, with PKTSTAT = 1: The threshold is stored in PFC9:0. The PF is asserted when the number of bytes written into the current packet in the FIFO is less than/equal to (DECIS = 0) or greater than/equal to (DECIS = 1) the threshold.
- 3. For IN packets, with PKTSTAT = 0: The threshold is stored in two parts: PKTS2:0 holds the number of committed packets, and PFC9:0 holds the number of bytes in the current packet. The PF is asserted when the FIFO is at or less full than (DECIS = 0), or at or more full than (DECIS = 1), the threshold.

#### 3.7.8 Command Protocol

An address of [1 0 0] on FIFOADR [2:0] will select the command interface. The command interface is used to write to and read from the *SX2* registers and the Endpoint 0 buffer, as well as the descriptor RAM. Command read and write transactions occur over FD[7:0] only. Each byte written to the *SX2* is either an address or a data byte, as determined by bit7. If bit7 = 1, then the byte is considered an address byte. If bit7 = 0, then the byte is considered a data byte. If bit7 = 1, then bit6 determines whether the address byte is a read request or a write request. If bit6 = 1, then the byte is considered a read request. If bit6 = 0 then the byte is considered a write request. Bits [5:0] hold the register address of the request. The format of the command address byte is shown in *Table 3-4*.

Table 3-4. Command Address Byte

Address/Data#	Read/Write#	A5	A4	A3	A2	A1	A0
Bit 7	Bit 6	Bit 5	Bit 4	Bit 3	Bit 2	Bit 1	Bit 0

Each Write request is followed by two or more data bytes. If another address byte is received before both data bytes are received, the SX2 ignores the first address and any incomplete data transfers. The format for the data bytes is shown in *Table 3-5* and *Table 3-6*. Some registers take a series of bytes. Each byte is transferred using the same protocol.

Table 3-5. Command Data Byte One

Bit 7	Bit 6	Bit 5	Bit 4	Bit 3	Bit 2	Bit 1	Bit 0
0	X	X	X	D7	D6	D5	D4

Table 3-6. Command Data Byte Two

Bit 7	Bit 6	Bit 5	Bit 4	Bit 3	Bit 2	Bit 1	Bit 0
0	Х	Х	Х	D3	D2	D1	D0

The first command data byte contains the upper nibble of data, and the second command byte contains the lower nibble of data.

Note:

3. In indexed mode, the value of the FLAGx pins is indeterminate except when addressing a FIFO (FIFOADR[2:0]={000,001,010,011}).

#### 3.7.8.1 Write Request Example

Prior to writing to a register, two conditions must be met: FIFOADR[2:0] must hold [1 0 0], and the Ready line must be HIGH. The external master should not initiate a command if the READY pin is not in a HIgh state.

Example: to write the byte <10110000> into the IFCONFIG register (0x01), first send a command address byte as follows.

#### Table 3-7. Command Address Write Byte

Address/Data#	Read/Write#	A5	A4	A3	A2	A1	A0
1	0	0	0	0	0	0	1

- · The first bit signifies an address transfer.
- The second bit signifies that this is a write command.
- The next six bits represent the register address (000001 binary = 0x01 hex).

Once the byte has been received the SX2 pulls the READY pin low to inform the external master not to send any more information. When the SX2 is ready to receive the next byte, the SX2 pulls the READY pin high again. Next, the upper nibble of the data byte is written to the SX2 as follows.

#### Table 3-8. Command Data Write Byte One

ĺ	Address/Data#	Don't Care	Don't Care	Don't Care	D7	D6	D5	D4
ĺ	0	Х	Х	Х	1	0	1	1

- The first bit signifies that this is a data transfer.
- The next three are don't care bits.
- The next four bits hold the upper nibble of the transferred byte.

Next, the lower nibble of the data byte is written to the SX2:

### Table 3-9. Command Data Write Byte Two

Address/Data#	Don't Care	Don't Care	Don't Care	D3	D2	D1	D0
0	Х	Х	Х	0	0	0	0

At this point the entire byte <10110000> has been transferred to register 0x01 and the write sequence is complete.

### 3.7.8.2 Read Request Example

The Read cycle is simpler than the write cycle. The Read cycle consists of a read request from the external master to the SX2. For example, to read the contents of register 0x01, a command address byte is written to the SX2 as follows.

Table 3-10. Command Address Read Byte

Ad	ddress/Data#	Read/Write#	A5	A4	A3	A2	A1	A0
	1	1	0	0	0	0	0	1

When the data is ready to be read, the SX2 asserts the INT# pin to tell the external master that the data it requested is waiting on FD[7:0].<sup>[4]</sup>

### 4.0 Enumeration

The SX2 has two modes of enumeration. The first mode is automatic through EEPROM boot load, as described in section 3.3. The second method is a manual load of the descriptor or VID, PID, and DID as described below.

#### 4.1 Standard Enumeration

The SX2 has 500 bytes of descriptor RAM into which the external master may write its descriptor. The descriptor RAM is accessed through register 0x30. To load a descriptor, the external master does the following:

- Initiate a Write Request to register 0x30.
- Write two bytes (four command data transfers) that define the length of the entire descriptor about to be transferred. The LSB is written first, followed by the MSB.<sup>[5]</sup>
- Write the descriptor, one byte at a time until complete. [5] Note: the register address is only written once.

#### Notes:

- 4. An important note: Once the SX2 receives a Read request, the SX2 allocates the interrupt line solely for the read request. If one of the six interrupt sources described in Section 3.4 is asserted, the SX2 will buffer that interrupt until the read request completes.
- 5. These and all other data bytes must conform to the command protocol.

After the entire descriptor has been transferred, the SX2 will float the pull-up resistor connected to D+, and parse through the descriptor to locate the individual descriptors. After the SX2 has parsed the entire descriptor, the SX2 will connect the pull-up resistor and enumerate automatically. When enumeration is complete, the SX2 will notify the external master with an ENUMOK interrupt.

The format and order of the descriptor should be as follows (see Section 12.0 for an example):

- · Device.
- Device qualifier.
- High-speed configuration, high-speed interface, high-speed endpoints.
- Full-speed configuration, full-speed interface, full-speed endpoints.
- · Strings.

#### 4.2 Default Enumeration

The external master may simply load a VID, PID, and DID and use the default descriptor built into the SX2. To use the default descriptor, the descriptor length described above must equal 6. After the external master has written the length, the VID, PID, and DID must be written LSB, then MSB. For example, if the VID, PID, and DID are 0x04B4, 0x1002, and 0x0001 respectively, then the external master does the following:

- Initiates a Write Request to register 0x30.
- Writes two bytes (four command data transfers) that define the length of the entire descriptor about to be transferred. In this case, the length is always six.
- Writes the VID, PID, and DID bytes: 0xB4, 0x04, 0x02, 0x10, 0x01, 0x00 (in nibble format per the command protocol).

The default descriptor is listed in Section 12.0. The default descriptor can be used as a starting point for a custom descriptor.

### 5.0 Endpoint 0

The SX2 will automatically respond to USB chapter 9 requests without any external master intervention. If the SX2 receives a request to which it cannot respond automatically, the SX2 will notify the external master. The external master then has the choice of responding to the request or stalling.

After the SX2 receives a set-up packet to which it cannot respond automatically, the SX2 will assert a SETUP interrupt. After the external master reads the Interrupt Status Byte to determine that the interrupt source was the SETUP interrupt, it can initiate a read request to the SETUP register, 0x32. When the SX2 sees a read request for the SETUP register, it will present the first byte of set-up data to the external master. Each additional read request will present the next byte of set-up data, until all eight bytes have been read.

The external master can stall this request at this or any other time. To stall a request, the external master initiates a write request for the SETUP register, 0x32, and writes any non-zero value to the register.

If this set-up request has a data phase, the SX2 will then interrupt the external master with an EP0BUF interrupt when the buffer becomes available. The SX2 determines the direction of the set-up request and interrupts when either:

- IN: the Endpoint 0 buffer becomes available to write to, or
- OUT: the Endpoint 0 buffer receives a packet from the USB host.

For an IN set-up transaction, the external master can write up to 64 bytes at a time for the data phase. The steps to write a packet are as follows:

- 1. Wait for an EP0BUF interrupt, indicating that the buffer is available.
- 2. Initiate a write request for register 0x31.
- 3. Write one data byte.
- 4. Repeat steps 2 and 3 until either all the data or 64 bytes have been written, whichever is less.
- 5. Write the number of bytes in this packet to the byte count register, 0x33.

To send more than 64 bytes, the process is repeated. The SX2 internally stores the length of the data phase that was specified in the wLength field (bytes 6,7) of the set-up packet. To send less than the requested amount of data, the external master writes a packet that is less than 64 bytes, or if a multiple of 64, the external master follows the data with a zero-length packet. When the SX2 sees a short or zero-length packet, it will complete the set-up transfer by automatically completing the handshake phase. The SX2 will not allow more data than the wLength field specified in the set-up packet. Note: the PKTEND pin does not apply to Endpoint 0. The only way to send a short or zero length packet is by writing to the byte count register with the appropriate value.

Document #: 38-08013 Rev. \*B Page 16 of 50

For an OUT set-up transaction, the external master can read each packet received from the USB host during the data phase. The steps to read a packet are as follows:

- 1. Wait for an EP0BUF interrupt, indicating that a packet was received from the USB host into the buffer.
- 2. Initiate a read request for the byte count register, 0x33. This indicates the amount of data received from the host.
- 3. Initiate a read request for register 0x31.
- 4. Read one byte.
- 5. Repeat steps 3 and 4 until the number of bytes specified in the byte count register has been read.

To receive more than 64 bytes, the process is repeated. The SX2 internally stores the length of the data phase that was specified in the wLength field of the set-up packet (bytes 6,7). When the SX2 sees that the specified number of bytes have been received, it will complete the set-up transfer by automatically completing the handshake phase. If the external master does not wish to receive the entire transfer, it can stall the transfer.

If the SX2 receives another set-up packet before the current transfer has completed, it will interrupt the external master with another SETUP interrupt.

If the SX2 receives a set-up packet with no data phase, the external master can accept the packet and complete the handshake phase by writing zero to the byte count register.

Table 6-1. SX2 Pin Descriptions

QFN Pin	SSOP Pin	Name	Туре	Default	Description
3	10	AVCC	Power	N/A	<b>Analog</b> $V_{CC}$ . This signal provides power to the analog section of the chip.
6	13	AGND	Power	N/A	Analog Ground. Connect to ground with as short a path as possible.
9	16	DMINUS	I/O/Z	Z	USB D- Signal. Connect to the USB D- signal.
8	15	DPLUS	I/O/Z	Z	USB D+ Signal. Connect to the USB D+ signal.
42	49	RESET#	Input	N/A	Active LOW Reset. Resets the entire chip. This pin is normally tied to $V_{CC}$ through a 100K resistor, and to GND through a 0.1- $\mu$ F capacitor.
5	12	XTALIN	Input	N/A	<b>Crystal Input</b> . Connect this signal to a 24-MHz parallel-resonant, fundamental mode crystal and 20-pF capacitor to GND. It is also correct to drive XTALIN with an external 24-MHz square wave derived from another clock source.
4	11	XTALOUT	Output	N/A	<b>Crystal Output</b> . Connect this signal to a 24-MHz parallel-resonant, fundamental mode crystal and 20-pF capacitor to GND. If an external clock is used to drive XTALIN, leave this pin open.
54	5	NC	Output	0	No Connect. This pin must be left unconnected.
33	40	READY	Output	L	<b>READY</b> is an output-only ready that gates external command reads and writes. Active High.
34	41	INT#	Output	Н	INT# is an output-only external interrupt signal. Active Low.
35	42	SLOE	Input	I	<b>SLOE</b> is an input-only output enable with programmable polarity (POLAR.4) for the slave FIFOs connected to FD[7:0] or FD[15:0].
36	43	FIFOADR2	Input	I	<b>FIFOADR2</b> is an input-only address select for the slave FIFOs connected to FD[7:0] or FD[15:0].
37	44	FIFOADR0	Input	I	<b>FIFOADR0</b> is an input-only address select for the slave FIFOs connected to FD[7:0] or FD[15:0].
38	45	FIFOADR1	Input	I	<b>FIFOADR1</b> is an input-only address select for the slave FIFOs connected to FD[7:0] or FD[15:0].
39	46	PKTEND	Input	I	<b>PKTEND</b> is an input-only packet end with programmable polarity (POLAR.5) for the slave FIFOs connected to FD[7:0] or FD[15:0].
40	47	FLAGD/C S#	CS#:I FLAGD:O	I	<b>FLAGD</b> is a programmable slave-FIFO output status flag signal. CS# is a master chip select (default).
18	25	FD[0]	I/O/Z	I	FD[0] is the bidirectional FIFO/Command data bus.
19	26	FD[1]	I/O/Z	I	FD[1] is the bidirectional FIFO/Command data bus.
20	27	FD[2]	I/O/Z	I	FD[2] is the bidirectional FIFO/Command data bus.
21	28	FD[3]	I/O/Z	I	FD[3] is the bidirectional FIFO/Command data bus.
22	29	FD[4]	I/O/Z	I	FD[4] is the bidirectional FIFO/Command data bus.
23	30	FD[5]	I/O/Z	I	FD[5] is the bidirectional FIFO/Command data bus.
24	31	FD[6]	I/O/Z	I	FD[6] is the bidirectional FIFO/Command data bus.
25	32	FD[7]	I/O/Z	I	FD[7] is the bidirectional FIFO/Command data bus.
45	52	FD[8]	I/O/Z	I	FD[8] is the bidirectional FIFO data bus.
46	53	FD[9]	I/O/Z	I	FD[9] is the bidirectional FIFO data bus.
47	54	FD[10]	I/O/Z	I	FD[10] is the bidirectional FIFO data bus.
48	55	FD[11]	I/O/Z	I	FD[11] is the bidirectional FIFO data bus.
49	56	FD[12]	I/O/Z	I	FD[12] is the bidirectional FIFO data bus.
50	1	FD[13]	I/O/Z	I	FD[13] is the bidirectional FIFO data bus.
51	2	FD[14]	I/O/Z	I	FD[14] is the bidirectional FIFO data bus.
52	3	FD[15]	I/O/Z	I	FD[15] is the bidirectional FIFO data bus.

Table 6-1. SX2 Pin Descriptions (continued)

<sup>\*</sup>Please note that the *SX2* was not designed to support dynamic modification of these endpoint configuration registers. If your applications need the ability to change endpoint configurations after the device has already enumerate with a specific configuration, please expect some delay in being able to access the FIFOs after changing the configuration. For example, after writing to EP2PKTLENL, you must wait for at least 35 us measured from the time the READY signal is asserted before writing to the FIFO. This delay time varies for different registers and is not characterized, because the *SX2* was not designed for this dynamic change of endpoint configuration registers.

### 7.1 IFCONFIG Register 0x01

IFCONFIG 0x01

Bit #	7	6	5	4	3	2	1	0
Bit Name	IFCLKSRC	3048MHZ	IFCLKOE	IFCLKPOL	ASYNC	STANDBY	FLAGD/CS#	DISCON
Read/Write	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Default	1	1	0	0	1	0	0	1

#### 7.1.1 Bit 7: IFCLKSRC

This bit selects the clock source for the FIFOs. If IFCLKSRC = 0, the external clock on the IFCLK pin is selected. If IFCLKSRC = 1 (default), an internal 30 or 48 MHz clock is used.

#### 7.1.2 Bit 6: 3048MHZ

This bit selects the internal FIFO clock frequency. If 3048MHZ = 0, the internal clock frequency is 30 MHz. If 3048MHZ = 1 (default), the internal clock frequency is 48 MHz.

#### 7.1.3 Bit 5: IFCLKOE

This bit selects if the IFCLK pin is driven. If IFCLKOE = 0 (default), the IFCLK pin is floated. If IFCLKOE = 1, the IFCLK pin is driven.

#### 7.1.4 Bit 4: IFCLKPOL

This bit controls the polarity of the IFCLK signal.

- When IFCLKPOL=0, the clock has the polarity shown in all the timing diagrams in this data sheet (rising edge is the activating edge).
- When IFCLKPOL=1, the clock is inverted (in some cases may help with satisfying data set-up times).

#### 7.1.5 Bit 3: ASYNC

This bit controls whether the FIFO interface is synchronous or asynchronous. When ASYNC = 0, the FIFOs operate synchronously. In synchronous mode, a clock is supplied either internally or externally on the IFCLK pin, and the FIFO control signals function as read and write enable signals for the clock signal.

When ASYNC = 1 (default), the FIFOs operate asynchronously. No clock signal input to IFCLK is required, and the FIFO control signals function directly as read and write strobes.

#### 7.1.6 Bit 2: STANDBY

This bit instructs the *SX2* to enter a low-power mode. When STANDBY=1, the *SX2* will enter a low-power mode by turning off its oscillator. The external master should write this bit after it receives a bus activity interrupt (indicating that the host has signaled a USB suspend condition). If *SX2* is disconnected from the USB bus, the external master can write this bit at any time to save power. Once suspended, the *SX2* is awakened either by resumption of USB bus activity or by assertion of its WAKEUP pin.

#### 7.1.7 Bit 1: FLAGD/CS#

This bit controls the function of the FLAGD/CS# pin. When FLAGD/CS# = 0 (default), the pin operates as a slave chip select. If FLAGD/CS# = 1, the pin operates as FLAGD.

#### 7.1.8 Bit 0: DISCON

This bit controls whether the internal pull-up resistor connected to D+ is pulled high or floating. When DISCON = 1 (default), the pull-up resistor is floating simulating a USB unplug. When DISCON=0, the pull-up resistor is pulled high signaling a USB connection.

### 7.2 FLAGSAB/FLAGSCD Registers 0x02/0x03

The SX2 has four FIFO flags output pins: FLAGA, FLAGB, FLAGC, FLAGD.

## FLAGSAB

0x02
------

Bit #	7	6	5	4	3	2	1	0
Bit Name	FLAGB3	FLAGB2	FLAGB1	FLAGB0	FLAGA3	FLAGA2	FLAGA1	FLAGA0
Read/Write	R/W							
Reset	0	0	0	0	0	0	0	0

Document #: 38-08013 Rev. \*B Page 22 of 50

FLAGSCD 0x03

Bit #	7	6	5	4	3	2	1	0
Bit Name	FLAGD3	FLAGD2	FLAGD1	FLAGD0	FLAGC3	FLAGC2	FLAGC1	FLAGC0
Read/Write	R/W							
Reset	0	0	0	0	0	0	0	0

These flags can be programmed to represent various FIFO flags using four select bits for each FIFO. The 4-bit coding for all four flags is the same, as shown in the following table.

Table 7-2. FIFO Flag 4-bit Coding

FLAGx3	FLAGx2	FLAGx1	FLAGx0	Pin Function
0	0	0	0	FLAGA = PF, FLAGB = FF, FLAGC = EF, FLAGD = CS# (actual FIFO is selected by FIFOADR[2:0] pins)
0	0	0	1	Reserved
0	0	1	0	Reserved
0	0	1	1	Reserved
0	1	0	0	EP2 PF
0	1	0	1	EP4 PF
0	1	1	0	EP6 PF
0	1	1	1	EP8 PF
1	0	0	0	EP2 EF
1	0	0	1	EP4 EF
1	0	1	0	EP6 EF
1	0	1	1	EP8 EF
1	1	0	0	EP2 FF
1	1	0	1	EP4 FF
1	1	1	0	EP6 FF
1	1	1	1	EP8 FF

For the default (0000) selection, the four FIFO flags are fixed-function as shown in the first table entry; the input pins FIFOADR[2:0] select to which of the four FIFOs the flags correspond. These pins are decoded as shown in *Table 3-3*.

The other (non-zero) values of FLAGx[3:0] allow the designer to independently configure the four flag outputs FLAGA-FLAGD to correspond to any flag-Programmable, Full, or Empty-from any of the four endpoint FIFOs. This allows each flag to be assigned to any of the four FIFOs, including those not currently selected by the FIFOADR [2:0] pins. For example, the external master could be filling the EP2IN FIFO with data while also checking the empty flag for the EP4OUT FIFO.

### 7.3 POLAR Register 0x04

This register controls the polarities of FIFO pin signals and the WAKEUP pin.

POLAR 0x04

Bit #	7	6	5	4	3	2	1	0
Bit Name	WUPOL	0	PKTEND	SLOE	SLRD	SLWR	EF	FF
Read/Write	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0

#### 7.3.1 Bit 7: WUPOL

This flag sets the polarity of the WAKEUP pin. If WUPOL = 0 (default), the polarity is active LOW. If WUPOL=1, the polarity is active HIGH.

### 7.3.2 Bit 5: PKTEND

This flag selects the polarity of the PKTEND pin. If PKTEND = 0 (default), the polarity is active LOW. If PKTEND = 1, the polarity is active HIGH.

Document #: 38-08013 Rev. \*B Page 23 of 50

### 7.3.3 Bit 4: SLOE

This flag selects the polarity of the SLOE pin. If SLOE = 0 (default), the polarity is active LOW. If SLOE = 1, the polarity is active HIGH. This bit can only be changed by using the EEPROM configuration load.

#### 7.3.4 Bit 3: SLRD

This flag selects the polarity of the SLRD pin. If SLRD = 0 (default), the polarity is active LOW. If SLRD = 1, the polarity is active HIGH. This bit can only be changed by using the EEPROM configuration load.

### 7.3.5 SLWR Bit 2

This flag selects the polarity of the SLWR pin. If SLWR = 0 (default), the polarity is active LOW. If SLWR = 1, the polarity is active HIGH. This bit can only be changed by using the EEPROM configuration load.

#### 7.3.6 EF Bit 1

This flag selects the polarity of the EF pin (FLAGA/B/C/D). If EF = 0 (default), the EF pin is pulled low when the FIFO is empty. If EF = 1, the EF pin is pulled HIGH when the FIFO is empty.

#### 7.3.7 FF Bit 0

This flag selects the polarity of the FF pin (FLAGA/B/C/D). If FF = 0 (default), the FF pin is pulled low when the FIFO is full. If FF = 1, the FF pin is pulled HIGH when the FIFO is full.

### 7.4 REVID Register 0x05

These register bits define the silicon revision.

REVID 0x05

Bit #	7	6	5	4	3	2	1	0
Bit Name	Major	Major	Major	Major	Minor	Minor	Minor	Minor
Read/Write	R/W							
Reset	X	X	Х	X	X	X	X	X

The upper nibble is the major revision. The lower nibble is the minor revision. For example: if REVID = 0x11, then the silicon revision is 1.1.

### 7.5 EPxCFG Register 0x06-0x09

These registers configure the large, data-handling *SX2* endpoints, EP2, 4, 6, and 8. *Figure 3-1* shows the configuration choices for these endpoints. Shaded blocks group endpoint buffers for double-, triple-, or quad-buffering. The endpoint direction is set independently—any shaded block can have any direction.

EPxCFG 0x06, 0x07, 0x08, 0x09

Bit #	7	6	5	4	3	2	1	0
Bit Name	VALID	DIR	TYPE1	TYPE0	SIZE	STALL	BUF1	BUF0
Read/Write	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	1	0	1	0	0	0	1	0

### 7.5.1 Bit 7: VALID

The external master sets VALID = 1 to activate an endpoint, and VALID = 0 to deactivate it. All SX2 endpoints default to valid. An endpoint whose VALID bit is 0 does not respond to any USB traffic.

#### 7.5.2 Bit 6: DIR

0 = OUT, 1 = IN. Defaults for EP2/4 are DIR = 0, OUT, and for EP6/8 are DIR = 1, IN.

#### 7.5.3 Bit [5,4]: TYPE1, TYPE0

These bits define the endpoint type, as shown in *Table 7-3*. The TYPE bits apply to all of the endpoint configuration registers. All *SX2* endpoints except EP0 default to BULK.

Table 7-3. Endpoint Type

TYPE1	TYPE0	Endpoint Type
0	0	Invalid
0	1	Isochronous
1	0	Bulk (Default)
1	1	Interrupt

### 7.5.4 Bit 3: SIZE

0 = 512 bytes (default), 1 = 1024 bytes.

Endpoints 4 and 8 can only be 512 bytes. The size of endpoints 2 and 6 is selectable.

### 7.5.5 Bit 2: STALL

Each bulk endpoint (IN or OUT) has a STALL bit (bit 2). If the external master sets this bit, any requests to the endpoint return a STALL handshake rather than ACK or NAK. The Get Status-Endpoint Request returns the STALL state for the endpoint indicated in byte 4 of the request. Note that bit 7 of the endpoint number EP (byte 4) specifies direction.

### 7.5.6 Bit [1,0]: BUF1, BUF0

The depth of endpoint buffering is selected via BUF1:0, as shown in Table 7-4.

Table 7-4. Endpoint Buffering

BUF1	BUF0	Buffering
0	0	Quad
0	1	Invalid
1	0	Double
1	1	Triple

### 7.6 EPxPKTLENH/L Registers 0x0A-0x11

The external master can use these registers to set smaller packet sizes than the physical buffer size (refer to the previously described EPxCFG registers). The default packet size is 512 bytes for all endpoints. Note that EP2 and EP6 can have maximum sizes of 1024 bytes, and EP4 and EP8 can have maximum sizes of 512 bytes, to be consistent with the endpoint structure.

In addition, the EPxPKTLENH register has four other endpoint configuration bits.

0x0B, 0x0D, 0x0F, 0x11

Bit #	7	6	5	4	3	2	1	0
Bit Name	PL7	PL6	PL5	PL4	PL3	PL2	PL1	PL0
Read/Write	R/W							
Reset	0	0	0	0	0	0	0	0

### EP2PKTLENH, EP6PKTLENH 0x0A, 0x0E

Bit #	7	6	5	4	3	2	1	0
Bit Name	INFM1	OEP1	ZEROLEN	WORDWIDE	0	PL10	PL9	PL8
Read/Write	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	1	1	0	0	1	0

### **EP4PKTLENH, EP8PKTLENH** 0x0C, 0x10

Bit #	7	6	5	4	3	2	1	0
Bit Name	INFM1	OEP1	ZEROLEN	WORDWIDE	0	0	PL9	PL8
Read/Write	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	1	1	0	0	1	0

Document #: 38-08013 Rev. \*B Page 25 of 50

### 7.6.1 Bit 7: INFM1 EPxPKTLENH.7

When the external master sets INFM = 1 in an endpoint configuration register, the FIFO flags for that endpoint become valid one sample earlier than when the full condition occurs. These bits take effect only when the FIFOs are operating synchronously according to an internally or externally supplied clock. Having the FIFO flag indications one sample early simplifies some synchronous interfaces. This applies only to IN endpoints. Default is INFM1 = 0.

#### 7.6.2 Bit 6: OEP1 EPxPKTLENH.6

When the external master sets an OEP = 1 in an endpoint configuration register, the FIFO flags for that endpoint become valid one sample earlier than when the empty condition occurs. These bits take effect only when the FIFOs are operating synchronously according to an internally or externally supplied clock. Having the FIFO flag indications one sample early simplifies some synchronous interfaces. This applies only to OUT endpoints. Default is OEP1 = 0.

#### 7.6.3 Bit 5: ZEROLEN EPxPKTLENH.5

When ZEROLEN = 1 (default), a zero length packet will be sent when the PKTEND pin is asserted and there are no bytes in the current packet. If ZEROLEN = 0, then a zero length packet will not be sent under these conditions.

#### 7.6.4 Bit 4: WORDWIDE EPxPKTLENH.4

This bit controls whether the data interface is 8 or 16 bits wide. If WORDWIDE = 0, the data interface is eight bits wide, and FD[15:8] have no function. If WORDWIDE = 1 (default), the data interface is 16 bits wide.

### 7.6.5 Bit [2..0]: PL[X:0] Packet Length Bits

The default packet size is 512 bytes for all endpoints.

### 7.7 EPxPFH/L Registers 0x12-0x19

The Programmable Flag registers control when the PF goes active for each of the four endpoint FIFOs: EP2, EP4, EP6, and EP8. The EPxPFH/L fields are interpreted differently for OUT and IN endpoints.

#### EP2PFL, EP4PFL, EP6PFL, EP8PFL

0x13, 0x15, 0x17, 0x19

Bit #	7	6	5	4	3	2	1	0
Bit Name	PFC7	PFC6	PFC5	PFC4	PFC3	PFC2	PFC1	PFC0
Read/Write	R/W							
Reset	0	0	0	0	0	0	0	0

**EP2PFH**, **EP6PFH** 0x12. 0x16

,								,
Bit #	7	6	5	4	3	2	1	0
Bit Name	DECIS	PKTSTAT	INPKTS[2] OUT:PFC12	INPKTS[1] OUT:PFC11	INPKTS[0] OUT:PFC10	0	0	PFC8
Read/Write	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	1	0	0	0	1	0	0	0

**EP4PFH, EP8PFH** 0x14, 0x18

Bit #	7	6	5	4	3	2	1	0
Bit Name	DECIS	PKTSTAT	INPKTS[2] OUT:PFC12	INPKTS[1] OUT:PFC11	INPKTS[0] OUT:PFC10	0	0	PFC8
Read/Write	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	1	0	0	0

#### 7.7.1 DECIS EPxPFH.7

If DECIS = 0, then PF = 1 when the byte count < = PF. If DECIS = 1 (default), then PF = 1 when the byte count > = PF. For OUT endpoints, the byte count is the total number of bytes in the FIFO that are available to the external master. For IN endpoints, the byte count is determined by the PKSTAT bit.

#### 7.7.2 PKSTAT EPxPFH.6

If PKTSTAT = 0 (default), the PF refers to the entire IN endpoint FIFO. If PKTSTAT = 1, the PF refers to the current packet. For IN endpoints, the PF can apply to either the entire FIFO, comprising multiple packets, or only to the current packet being filled.

Document #: 38-08013 Rev. \*B Page 26 of 50

PKTSTAT	PF applies to	EPnPFH:L format
0	Number of committed packets + current packet bytes	PKTS[] PFC[]
1	Current packet bytes only	PFC[]

#### 7.7.3 IN:PKTS(2:0)/OUT:PFC[12:10] EPxPFH[5:3]

These three bits have a different meaning, depending on whether this is an IN or OUT endpoint, and if IN endpoint, the value of the PKTSTAT bit.

#### 7.7.3.1 IN Endpoints

When PKTSTAT = 0 (default), the PF considers when there are PKTS packets plus PFC bytes in the FIFO. PKTS(2:0) determines how many packets are considered, according to the following table.

Table 7-5. PKTS Bits

PKTS2	PKTS1	PKTS0	Number of packets
0	0	0	0
0	0	1	1
0	1	0	2
0	1	1	3
1	0	0	4

When PKTSTAT = 1, the PF considers when there are PFC bytes in the FIFO, no matter how many packets are in the FIFO. The PKTS(2:0) bits are ignored.

### 7.7.3.2 OUT Endpoints

The PF considers when there are PFC bytes in the FIFO.

### 7.8 EPxISOINPKTS Registers 0x1A-0x1D

#### EP2ISOINOKTS, EP4ISOINPKTS, EP6ISOINPKTS, EP8ISOINPKTS

0x1A, 0x1B, 0x1C, 0x1D

Bit #	7	6	5	4	3	2	1	0
Bit Name	0	0	0	0	0	INPPF2	INPPF1	INPPF0
Read/Write	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	1

For ISOCHRONOUS IN endpoints only, these registers determine the number of packets per frame (only one per frame for full-speed mode) or microframe (up to three per microframe for high-speed mode), according to the following table.

Table 7-6. EPxISOINPKTS

INPPF1	INPPF0	Packets
0	0	Invalid
0	1	1 (default)
1	0	2
1	1	3

### 7.9 EPxxFLAGS Registers 0x1E-0x1F

The EPxxFLAGS provide an alternate way of checking the status of the endpoint FIFO flags. If enabled, the *SX2* can interrupt the external master when a flag is asserted, and the external master can read these two registers to determine the state of the FIFO flags. If the INFM1 and/or OEP1 bits are set, then the EPxEF and EPxFF bits are actually empty +1 and full -1.

EP24FLAGS 0x1E

Bit #	7	6	5	4	3	2	1	0
Bit Name	0	EP4PF	EP4EF	EP4FF	0	EP2PF	EP4EF	EP4FF
Read/Write	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	1

Document #: 38-08013 Rev. \*B Page 27 of 50

EP68FLAGS 0x1F

Bit #	7	6	5	4	3	2	1	0
Bit Name	0	EP8PF	EP8EF	EP8FF	0	EP6PF	EP6EF	EP6FF
Read/Write	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	1

### 7.9.1 EPxPF Bit 6, Bit 2

This bit is the current state of endpoint x's programmable flag.

#### 7.9.2 EPxEF Bit 5. Bit 1

This bit is the current state of endpoint x's empty flag. EPxEF = 1 if the endpoint is empty.

#### 7.9.3 EPxFF Bit 4, Bit 0

This bit is the current state of endpoint x's full flag. EPxFF = 1 if the endpoint is full.

### 7.10 INPKTEND/FLUSH Register 0x20

This register allows the external master to duplicate the function of the PKTEND pin. The register also allows the external master to selectively flush endpoint FIFO buffers..

INPKTEND/FLUSH 0x20

Bit #	7	6	5	4	3	2	1	0
Bit Name	FIFO8	FIFO6	FIFO4	FIFO2	EP3	EP2	EP1	EP0
Read/Write	W	W	W	W	W	W	W	W
Reset	0	0	0	0	0	0	0	0

Bit [4..7]: These bits allows the external master to selectively flush any or all of the endpoint FIFOs. By writing the desired endpoint FIFO bit, *SX2* logic flushes the selected FIFO. For example setting bit 7 flushes endpoint 8 FIFO.

Bit [3..0]: These bits are is used only for IN transfers. By writing the desired endpoint number (2,4,6 or 8), SX2 logic automatically commits an IN buffer to the USB host. For example, for committing a packet through endpoint 6, set the lower nibble to 6: set bits 1 and 2 high.

### 7.11 USBFRAMEH/L Registers 0x2A, 0x2B

Every millisecond, the USB host sends an SOF token indicating "Start Of Frame," along with an 11-bit incrementing frame count. The SX2 copies the frame count into these registers at every SOF.

USBFRAMEH 0x2A

Bit #	7	6	5	4	3	2	1	0
Bit Name	0	0	0	0	0	FC10	FC9	FC8
Read/Write	R	R	R	R	R	R	R	R
Reset	X	X	Х	X	Х	X	X	x

USBFRAMEL 0x2B

Bit #	7	6	5	4	3	2	1	0
Bit Name	FC7	FC6	FC5	FC4	FC3	FC2	FC1	FC0
Read/Write	R	R	R	R	R	R	R	R
Reset	Х	Х	X	X	Х	Х	Х	X

One use of the frame count is to respond to the USB SYNC\_FRAME Request. If the SX2 detects a missing or garbled SOF, the SX2 generates an internal SOF and increments USBFRAMEL–USBRAMEH.

Document #: 38-08013 Rev. \*B Page 28 of 50

### 7.12 MICROFRAME Registers 0x2C

MICROFRAME 0x2C

Bit #	7	6	5	4	3	2	1	0
Bit Name	0	0	0	0	0	MF2	MF1	MF0
Read/Write	R	R	R	R	R	R	R	R
Reset	Х	Х	X	X	X	Х	Х	х

MICROFRAME contains a count 0-7 that indicates which of the 125 microsecond microframes last occurred.

This register is active only when SX2 is operating in high-speed mode (480 Mbits/sec).

### 7.13 FNADDR Register 0x2D

During the USB enumeration process, the host sends a device a unique 7-bit address that the *SX2* copies into this register. There is normally no reason for the external master to know its USB device address because the *SX2* automatically responds only to its assigned address.

FNADDR 0x2D

Bit #	7	6	5	4	3	2	1	0
Bit Name	HSGRANT	FA6	FA5	FA4	FA3	FA2	FA1	FA0
Read/Write	R	R	R	R	R	R	R	R
Reset	X	X	Х	X	X	Х	X	Х

Bit 7: HSGRANT, Set to 1 if the SX2 enumerated at high speed. Set to 0 if the SX2 enumerated at full speed.

Bit[6..0]: Address set by the host.

### 7.14 INTENABLE Register 0x2E

This register is used to enable/disable the various interrupt sources, and by default all interrupts are enabled.

ITENABLE 0x2E

Bit #	7	6	5	4	3	2	1	0
Bit Name	SETUP	EP0BUF	FLAGS	ENUMOK	1	1	BUSACTIVITY	READY
Read/Write	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	1	1	1	1	1	1	1	1

#### 7.14.1 SETUP Bit 7

Setting this bit to a 1 enables an interrupt when a set-up packet is received from the USB host.

### 7.14.2 EP0BUF Bit 6

Setting this bit to a 1 enables an interrupt when the Endpoint 0 buffer becomes available.

#### 7.14.3 FLAGS Bit 5

Setting this bit to a 1 enables an interrupt when an OUT endpoint FIFO's state transitions from empty to not-empty.

### 7.14.4 ENUMOK Bit 2

Setting this bit to a 1 enables an interrupt when SX2 enumeration is complete.

### 7.14.5 BUSACTIVITY Bit 1

Setting this bit to a 1 enables an interrupt when the SX2 detects an absence or presence of bus activity.

#### 7.14.6 READY Bit 0

Setting this bit to a 1 enables an interrupt when the SX2 has powered on and performed an internal self-test.

Document #: 38-08013 Rev. \*B Page 29 of 50

### 7.15 DESC Register 0x30

This register address is used to write the 500-byte descriptor RAM. The external master writes two bytes (four command data transfers) to this address corresponding to the length of the descriptor or VID/PID/DID data to be written. The external master then consecutively writes that number of bytes into the descriptor RAM in nibble format. For complete details, refer to Section 4.0.

### 7.16 EP0BUF Register 0x31

This register address is used to access the 64-byte Endpoint 0 buffer. The external master can read or write to this register to complete Endpoint 0 data transfers. For complete details, refer to Section 5.0.

### 7.17 SETUP Register 0x32

This register address is used to access the 8-byte set-up packet received from the USB host. If the external master writes to this register, it can stall Endpoint 0. For complete details, refer to Section 5.0.

### 7.18 EP0BC Register 0x33

This register address is used to access the byte count of Endpoint 0. For Endpoint 0 OUT transfers, the external master can read this register to get the number of bytes transferred from the USB host. For Endpoint 0 IN transfers, the external master writes the number of bytes in the Endpoint 0 buffer to transfer the bytes to the USB host. For complete details, refer to Section 5.0.

Parameter	Description	Min.	Max.	Unit
t <sub>OEon</sub>	SLOE assert to FIFO DATA Output		10.5	ns
t <sub>OEoff</sub>	SLOE deassert to FIFO DATA Hold		10.5	ns

#### 11.6 Sequence Diagram

## 11.6.1 Single and Burst Synchronous Read Example

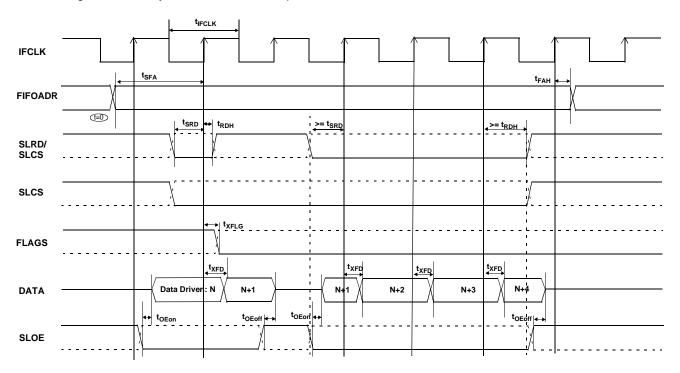

Figure 11-15. Slave FIFO Synchronous Read Sequence and Timing Diagram

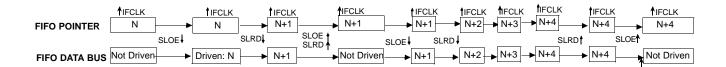

Figure 11-16. Slave FIFO Synchronous Sequence of Events Diagram

Document #: 38-08013 Rev. \*B Page 40 of 50

The above sequence diagrams show the timing relation between various SLAVE FIFO signals while performing a read from the FIFO in synchronous mode where the IFCLK is the clock source. The diagram shows a single read followed by a burst read.

- At t = 0 the FIFO address is set. Note that t<sub>SFA</sub> being 25 ns implies that the FIFO address lines need to be set up a clock cycle
  prior to a read.
- Then the SLOE is asserted. This causes the data lines to be in a driven state with the data that the FIFO pointer is currently
  pointing to. In this case of the above example it is the first byte in the FIFO. Note that the data is pre-fetched and is output only
  when the SLOE is asserted. SLOE is an output enable only. It has no other functions besides enabling the data bus to be in
  a driven state.
- The SLRD and SLCS is then asserted at the same time. The SLRD must meet the setup time of t<sub>SRD</sub> from the rising edge of the clock and must maintain the hold time of t<sub>RDH</sub> from the rising edge of IFCLK. If SLCS is used then, SLCS must be in an asserted state when SLRD is also asserted. When SLCS is used, the internal logic basically ANDs these two signal to determine a valid condition. Hence these signals can also be tied together.
- The FIFO pointer is updated on each rising edge of the IFCLK while the SLRD is in an asserted state. This data pointed to by the updated FIFO pointer is than output after a propagation delay of t<sub>XFD</sub> from the rising edge of the IFCLK. So in the above diagram data N is the first byte read from the FIFO. When the SLRD is asserted, in order to have the data output on the FIFO data bus, the SLOE MUST be in an asserted state also. The SLRD and SLOE can also be tied together.

For a burst read the SLRD and SLOE is left asserted during the entire duration of read of all the required bytes. In this burst read mode, when the SLOE is asserted the data output is the one that the FIFO pointer is pointing to. In this case after the first single read the FIFO pointer now points to N+1. After the SLRD is asserted, the FIFO pointer is incremented on the immediate rising edge of the IFCLK when the prefetched data is also output on the data bus. The FIFO pointer is incremented on each subsequent rising edge of the IFCLK while the SLRD is in an asserted state.

#### 11.6.2 Single and Burst Synchronous Write

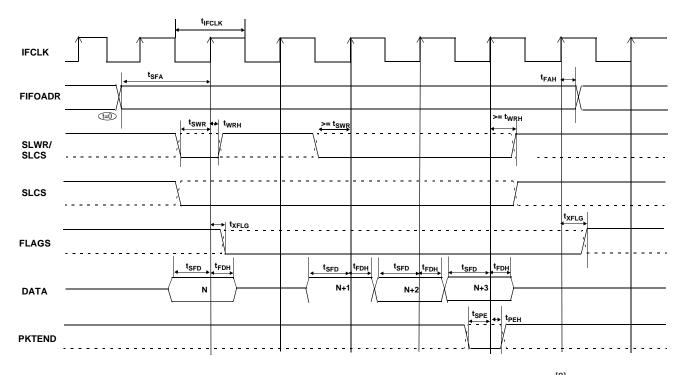

Figure 11-17. Slave FIFO Synchronous Write Sequence and Timing Diagram<sup>[8]</sup>

The above sequence diagram shows the timing relation between various signals while performing a write to the FIFO in synchronous mode where the IFCLK is the clock source. The diagram shows a single write followed by burst write of 3 bytes and committing the 4 bytes short packet using the PKTEND pin.

- At t = 0 the FIFO address is set. Note that t<sub>SFA</sub> being 25 ns implies that the FIFO address lines need to be set up a clock cycle prior to a read.
- Data is then written to the data bus t<sub>SFD</sub> before the rising edge of the IFCLK to meet the data setup time.
- ullet SLWR and SLCS are asserted at the same time. The SLWR must meet the setup time of  $t_{SWR}$  from the rising edge of the clock and must maintain the hold time of  $t_{WRH}$  measured from the rising edge of IFCLK. If SLCS is used then, SLCS must be in an

Document #: 38-08013 Rev. \*B Page 41 of 50

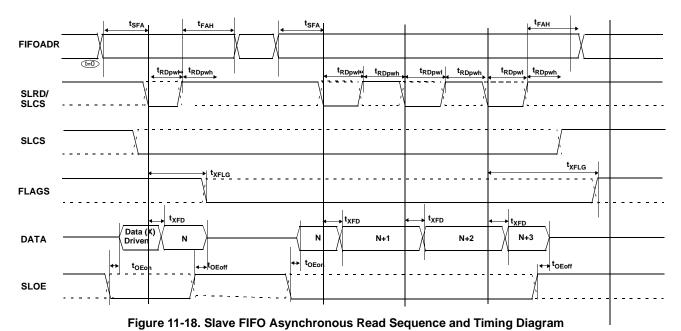

asserted state when SLWR is also asserted. The internal logic ANDs these two signals to determine a valid condition. Hence these signals can also be tied together.

Asserting the SLWR causes the data on the data bus to be written to the FIFO and the FIFO pointer incremented. The flag is
also updated after t<sub>XFLG</sub> from the rising edge of the clock.

For a burst write the SLWR is left asserted during the entire duration of writing all the required bytes. In this burst write mode once the SLWR is asserted the data on the FIFO data bus is written to the FIFO on every rising edge of the IFLCLK. The FIFO pointer is also updated on each rising edge of the IFCLK. In the above diagram once the four bytes are written to the FIFO, the SLWR is de-asserted. The short 4-byte packet can be committed to the host using the PKTEND pin.

There is no specific timing requirement that needs to be met for asserting PKTEND pin with regards to asserting SLWR signal. The PKTEND pin can be asserted anytime. In the scenario above the number of packets committed include the byte written last to the FIFO on the same rising edge of the IFCLK as the PKTEND is asserted. The FIFOADDR lines should be held constant during the PKTEND pin assertion.

#### 11.6.3 Sequence Diagram of a Single and Burst Asynchronous Read

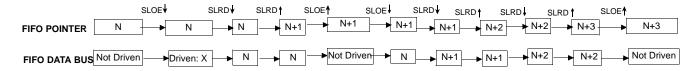

Figure 11-19. Slave FIFO Asynchronous Read Sequence of Events Diagram

The above sequence and timing diagram shows the timing relation between various signals while performing a read from the FIFO in asynchronous mode. The diagram shows a single read followed by a burst read.

- At t = 0 the FIFO address is set.
- SLOE is asserted. This causes the data lines to be in a driven state. The data output is the previous data, whatever was output last time around.
- The SLRD and SLCS is asserted at the same time. The SLRD must meet the minimum active pulse of t<sub>RDpwl</sub> and minimum de-active pulse width of t<sub>RDpwh</sub>. If SLCS is used then, SLCS must be in an asserted state when SLRD is also asserted. The internal logic basically ANDs these two signal to determine a valid condition. Hence these signals can be tied together.
- The data that is output on asserting the SLRD is the actual data from the FIFO. This data is output after a propagation delay
  of t<sub>XFD</sub> from the activating edge of the SLRD. So in the above diagram data N is the actual first byte data read from the FIFO.
  When the SLRD is asserted, in order to have the data output on the FIFO data bus, the SLOE MUST be in an asserted state
  also. The SLRD and SLOE can also be tied together.

In burst read mode when the SLRD is asserted, the data is in a driven state and is the previous data. Once SLRD is asserted, the data from the FIFO is output on the data bus (when SLOE is also in an asserted state) and the FIFO pointer is incremented. Basically the data is fetched at the time of the read.

#### 11.6.4 Sequence Diagram of a Single and Burst Asynchronous Write

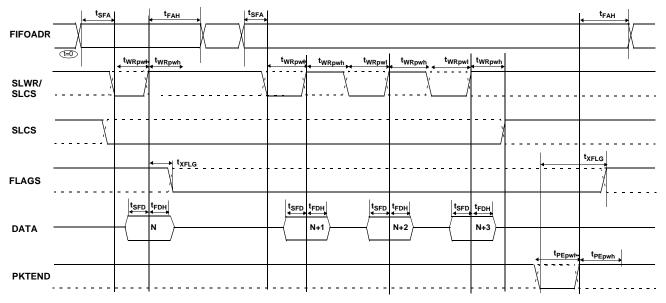

Figure 11-20. Slave FIFO Asynchronous Write Sequence and Timing Diagram<sup>[8]</sup>

The above sequence diagram shows the timing relation between various signals while performing a write to the FIFO in asynchronous mode. The diagram shows a single write followed by burst write of 3 bytes and committing the 4-bytes-short packet using the PKTEND pin.

- At t = 0 the FIFO address is set making sure that it meets the setup time of t<sub>SFA</sub>
- SLWR and SLCS is asserted at the same time. The SLWR must meet the minimum active pulse of t<sub>WRpwl</sub> and minimum
  deactive pulse width of t<sub>WRpwh</sub>. If SLCS is used then, SLCS must be in an asserted state when SLWR is also asserted. The
  internal logic basically ANDs these two signal to determine a valid condition. Hence these signals can be tied together.
- Data is then written to the data bus t<sub>SFD</sub> before the deasserting edge of the SLWR to meet the data setup time.
- De-asserting the SLWR causes the data on the data bus to be written to the FIFO and the FIFO pointer incremented. The flag
  is also updated after t<sub>XFLG</sub> from the deasserting edge of SLWR.

In this burst write mode once SLWR is deasserted, the data is written to the FIFO and the FIFO pointer is incremented. Asserting the SLWR causes the data to be written to the FIFO and the FIFO pointer to be incremented to point to the next byte in the FIFO. The FIFO pointer is post incremented.

In the above diagram once the four bytes are written to the FIFO and the SLWR is de-asserted, the short 4-byte packet can be committed to the host using the PKTEND pinl. The external device should be designed so as to not have SLWR and PKTEND pulsed at the same time. It should be designed so as to assert the PKTEND pin after the SLWR is deasserted and met the minimum deasserted pulse width. The FIFOADDR lines should be held constant during the PKTEND pin assertion.

## 13.0 General PCB Layout Guidelines<sup>[2]</sup>

The following recommendations should be followed to ensure reliable high-performance operation.

- · At least a four-layer impedance controlled boards are required to maintain signal quality.
- Specify impedance targets (ask your board vendor what they can achieve).
- To control impedance, maintain trace widths and trace spacing.
- Minimize stubs to minimize reflected signals.
- Connections between the USB connector shell and signal ground must be done near the USB connector.
- Bypass/flyback caps on VBus, near connector, are recommended.
- DPLUS and DMINUS trace lengths should be kept to within 2 mm of each other in length, with preferred length of 20-30 mm.
- Maintain a solid ground plane under the DPLUS and DMINUS traces. Do not allow the plane to be split under these traces.
- It is preferred to have no vias placed on the DPLUS or DMINUS trace routing.
- Isolate the DPLUS and DMINUS traces from all other signal traces by no less than 10 mm.

#### 14.0 Quad Flat Package No Leads (QFN) Package Design Notes

Electrical contact of the part to the Printed Circuit Board (PCB) is made by soldering the leads on the bottom surface of the package to the PCB. Hence, special attention is required to the heat transfer area below the package to provide a good thermal bond to the circuit board. A Copper (Cu) fill is to be designed into the PCB as a thermal pad under the package. Heat is transferred from the SX2 through the device's metal paddle on the bottom side of the package. Heat from here, is conducted to the PCB at the thermal pad. It is then conducted from the thermal pad to the PCB inner ground plane by a 5 x 5 array of via. A via is a plated through hole in the PCB with a finished diameter of 13 mil. The QFN's metal die paddle must be soldered to the PCB's thermal pad. Solder mask is placed on the board top side over each via to resist solder flow into the via. The mask on the top side also minimizes outgassing during the solder reflow process.

For further information on this package design please refer to the application note "Surface Mount Assembly of AMKOR's MicroLeadFrame (MLF) Technology." This application note can be downloaded from AMKOR's website from the following URL http://www.amkor.com/products/notes\_papers/MLF\_AppNote\_0902.pdf. The application note provides detailed information on board mounting guidelines, soldering flow, rework process, etc.

Figure 14-1 below display a cross-sectional area underneath the package. The cross section is of only one via. The solder paste template needs to be designed to allow at least 50% solder coverage. The thickness of the solder paste template should be 5 mil. It is recommended that "No Clean" type 3 solder paste is used for mounting the part. Nitrogen purge is recommended during reflow.

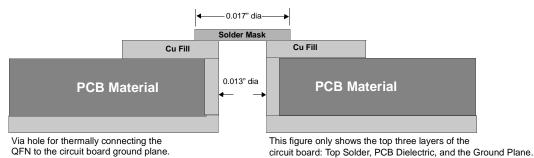

Figure 14-1. Crosssection of the Area Underneath the QFN Package

Figure 14-2a is a plot of the solder mask pattern and Figure 14-2b displays an X-Ray image of the assembly (darker areas indicate solder.

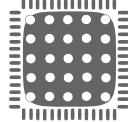

Figure 14-2. (a) Plot of the Solder Mask (White Area)

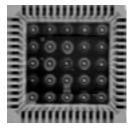

Figure 0-1. (b) X-ray Image of the Assembly
