## **More Architecture — Email Security**

- We want to secure email
- Generally, that requires crypto, which in turn requires protecting keys
- How shall we do that?

Steven M. Bellovin \_\_ November 15, 2007 \_\_ 1

## **Standard Techniques**

- Encrypt the private key with a user-typed passphrase
- Use special-purpose crypto hardware
- The latter is rarely available; we need to use the former, at least in some cases

## Where are Decryption and Signing Done?

- Gateway machine?
- End-user's machine?

Steven M. Bellovin \_\_ November 15, 2007 \_\_ 3

## Signing at the Gateway

- Tempting target
- Hard for user to supply the key or the passphrase
- How does the gateway know who sent the mail?
- Best for *organizational* signatures

## **Decrypting at the Gateway**

- Again, how are keys supplied?
- When is decryption done?
- Is the mail stored internally in the clear?

# Signing Every Message

- Suppose we want to sign every message
- Do we prompt users for a passphrase on each email sent?
- Rather annoying can we cache passphrases?

# (Why Sign Everything?)

- Principle?
- Prevent false attribution?
- Anti-spam?

Steven M. Bellovin \_\_ November 15, 2007 \_\_ 7

## **Caching Keys**

- If we cache keys, they're exposed to bugs in the mailer
- How risky are mailers?
- (How big are they?)

#### **Some Mailer Sizes**

Mailer	KLOC
Thunderbird	6000
Evolution	2500
(extras)	2200
Claws-Mail	840
Pine	530
Mutt	288

Numbers are *very* imprecise. All of these mailers require many libraries, especially the GUI mailers.

Steven M. Bellovin \_\_ November 15, 2007 \_\_ 9

# (Why are Mailers So Big?)

- Mail formats are complex
  - MIME
  - Multilingual
  - GUIs
- HTML rendering
- Other stuff bundled in (calendar, vCard, etc)
- Frequently include an editor

### Why are Mailers Insecure?

- Size
- Accept untrusted input
- Plenty of room for user error

### **Entrust our Keys to Mailers?**

- They're big and complicated
- They interact with lots of other programs
- They have long histories of security problems
- Handing them keys doesn't sound like a great idea...

## **Outboard Key Manager**

- Should we have a separate application to handle keys?
- How big are such applications?
- Can we trust them?

### **Key Managers**

Component	KLOC
GNOME Keyring	150
GNOME Keyring Manager	97
GPG	520
GPG2	737
pinentry	55

These aren't exactly tiny, either...

## **Bug Rates**

- How many bugs per 1,000 lines of code?
- Hard to measure
- Different types of software have different rates
- We can't count bugs that aren't found!

	Component	Bugs/KLOC
• That said	Linux 2.6 Kernel	.17
	Commercial code	20–30

## **Managing the Key Manager**

- The mailer still tells the key manager what to decrypt or sign
- If the mailer is buggy, it can fool the key manager
- You don't know what's *really* being signed or decrypted
- (This all applies to crypto hardware solutions, too)

### **Pure Outboard Solution?**

- Save inbound mail; manually decrypt it
- Edit outbound mail separately; manually sign, then paste that into mailer buffer
- Does this work?

## It's Too Inconvenient

- Most users *won't* put up with this
- Result: very few signed messages
- Result: reluctance to receive inbound encrypted messages
- Does this give us worse security?

### What Do We Do?

- There are no perfect solutions
- How disciplined are the users?
- How important is secure email?
- Can you have separate grades of keys?
- Who is your enemy?

## **Outboard Keys**

- Despite the risks, outboard keys are still better
- Still simpler than the mailer
- Less risk of key theft
- Easier to add (secure) audit trail

#### Windows Vista and IE 7

- Web browsers have also been problematic
- Internet Explorer has been worse...
- IE 7 on Vista is a lot better
- Why?

#### **Protected Mode**

- Run web browser with fewer privileges (exception: trusted sites can have full privileges)
- Compromise of the browser does not result in compromise of (most) user files

## Components

- User Account Control (UAC)
- Mandatory Integrity Control (MIC)
- User Interface Privilege Isolation (UIPI)

## **User Account Control**

- Eliminate need to log in as Administrator
- Even Administrator can run most applications without privilege they changed the privilege requirements for some operations
- Privilege can be raised as needed, with password entry. (Will users make that decision correctly?)

#### UAC

BierAtcourt	Control
If you starte	d this action, continue. Uninstall or change an application Microsoft Windows (FCC74877-EC3E-4DD8-A80B-008A702075A9)
Þ	
O Details	Continue Cancel
User Account	Control helps stop unauthorized changes to your computer.

The message is rather mysterious...

## **Mandatory Integrity Control**

- Low-privilege processes cannot write to protected files
- Available levels: low, medium, high
- Similar to MAC

## **Bell-Lapdula and MIC**

- Recall how Bell-Lapadula confidentiality mechanisms could be used for integrity protection, by reversing labels
- MIC uses half of it: it's really "no write down"
- MIC does not provide confidentiality protection

## **Privilege is Inherited**

- The privilege level of a process is inherited by its children
- Children spawned by protected mode IE also run at Low privilege
- This blocks attacks by ActiveX, VBScript, etc.

## Virtualization

- A lot of existing code wants to write files (cache, temporary files, cookies, history, registry, etc.)
- A shim layer virtualizes these functions
- Files to be modified in Low mode are copied to the Low area; the changes are made only to the copies

## **Gaining Privilege**

- Sometimes, Low processes need to do things requiring privilege
- Special *broker* processes will perform such operations on request
- Brokers ask user consent before proceeding
- Is that reliable?

## **Trusting the User?**

- Users can be tricked
- Many of today's dialog boxes are useless
- From a W3C glossary Wiki:

Dialog box: A window in which resides a button labeled "OK" and a variety of text and other content that users ignore.

## **Users Don't Like It**

- Some older applications break
- These were probably insecure to begin with
- But people are used to them

## **Lack of Confidentiality Protection**

- Low mode malware can still read your files
- It appears possible for Low mode applications to export data
- But full Bell-Lapadula confidentiality control is impractical
- Cookies are a special case prevent (some) cross-site scripting attacks

### **User Interface Privilege Isolation**

- Prevents Low mode processes for sending certain messages to higher-mode processes
- Blocks "shatter attack" (inject code into another process via Windows messages)
- In essence, ACL for message-passing

### What Has Microsoft Done?

- Separated Internet Explorer from Windows Explorer (i.e., restored the distinction between net and desktop)
- Used OS access controls to isolate browser
- Added more access controls
- Structural separation

## **Does it Work?**

- IE7 on Vista is immune to the .ani file (animated cursor) attack (see http://www.microsoft.com/technet/security/bulletin/ MS07-017.mspx)
- More precisely, the attack code couldn't escape the Low mode jail
- Human interface attacks may still be an issue
- Other delivery mechanisms for .ani still work

## Summary

- Structural separation helps
- It's not a panacea
- There are still challenging user interface issues
- Backwards compatibility is a problem
